I operated upon the left labyrinth on May 28th at 3.20 P.M., assisted by Mr. Lake and Dr. A. E. Peters. Gas-ether, followed by chloroform, was administered by Dr. F. E. Shipway. The auricle was turned down by Lake's method[2] and a preliminary radical mastoid operation was performed. The patient being of the short-necked, plethoric type, some difficulty was experienced in getting a wide opening, and this was added to by the hardness of the bone and the depth of the antrum. On clearing the buttress three sharp facial twitches were noted. The ossicles and membrane having been removed, including the stapes, the promontory was exposed and the cochlea opened with a fine chisel and cautiously cleared out in a direction towards the vestibule. The external semicircular canal was next opened and the posterior canal similarly treated; *the latter was* followed to the vestibule, which was scraped with a fine spoon. The ampullæ of the canals were scraped with a sharp, bent probe, and a probe was passed from the cochlear wound, through the vestibule, to the canal wound. The cochlea and vestibule were then swabbed out with a 2 per cent. solution of formalin, after which the auricle was readjusted and the wound lightly packed *viâ* the meatus. The patient passed an excellent night, sleeping very well. The temperature was 98·8° F. and the pulse was 112. On May 29th his temperature and pulse were 98·2° and 108 in the morning and 93·6° and 112 in the evening. He vomited until mid-day and was retching throughout the day, with intervals of sleep. He complained of slight tinnitus in both ears. There was no vertigo. He had left facial paralysis. On May 30th his temperature and pulse were 98·2° and 96 in the morning and 98·8° and 96 in the evening. There was still some retching. He had no tinnitus in the left ear, but it occurred once or twice slightly in the right. He did not sleep until past midnight. On one occasion he *got out of bed* alone and walked steadily and in these cases. The examination of the fæces is also important. Usually the quantity passed at each action of the bowels is small and it may consist of pulpy fragments and small lumps. Stools of small calibre, ribbon-like or thin as pencils and grooved, are very characteristic. Sometimes small cord-like mucous masses are passed and some degree of hæmorrhage occurs in certain cases, even in those of purely nervous type. The blood may be passed in larger or smaller quantities, generally at the end of defæcation, or there may be fragments of blood-stained mucus. In regard to the pathology Dr. Singer agrees with the view of Westphal that the spastic contracted condition of the intestine in the cases of nervous origin is due to a disturbed coördination of the muscular movements of the bowel. In regard to diagnosis, spastic constipation has to be differentiated from the various forms of colic, including lead colic, from gastric crises, and from intussusception and other forms of intestinal obstruction. The important features to recognise in this regard are the presence of sections of contracted bowel, the absence of pronounced meteorism and visible peristalsis. The treatment is a matter of considerable importance, since purgatives are to be avoided in spite of the constipation, their action tending to provoke or to increase the condition of spasm. In particular the drastic purgatives are harmful, and even cascara and saline aperients are, according to Dr. Singer, inadvisable. He also counsels against the use of mechanical procedures, such as massage and electrical methods of treatment. He states that the enemata of oil recommended by Fleiner are of value if used sufficiently warm. The application of moist heat to the abdomen he has also found very valuable. The most useful drug is belladonna in the form of suppositories, while bougies passed per anum are also strongly recommended by Dr. Singer. He uses the English form of rectal bougie, passed in a semi-soft condition with the patient in the knee-elbow position. The introduction is often painful at first and it may be necessary to use suppositories of codeine or belladonna. Considerable resistance is often met with at the internal sphincter and it is then necessary to allow the bougie to remain in contact with the obstruction for a time before it can be gradually pushed beyond it. Small bougies are to be used at first and later large ones. The question of diet does not appear to be one of importance in these cases, but in the nervous cases anything tending to lessen the excitability of the nervous system, such as change and rest cures, may be beneficial. Dr. Singer's paper affords an interesting study of an important condition.

[2] THE LANCET, Jan. 6th, 1906, p. 25.

THE PERILS OF FOOTBALL.

WITHIN a fortnight of the beginning of the football season we have received reports of three broken legs (death following in one of these cases) and one dislocated collar bone. Of course, this is not by any means a complete list of the serious injuries which have been sustained by football players since Sept. 1st, and in any case the full list would probably not be even a comparatively heavy one when the number of people actively taking part in the game is taken into consideration. But when sports may be associated with death it behoves all who are interested in those sports to do what they can to prevent accidents. We have on other occasions referred to the factors which are chiefly at work in rendering football dangerous. These factors are many. Essentially a game, whether the dribbling or running code be in question, where the greatest possible muscular exertion is called into play, and where, though the highest premium may be put on pace and skill, both strength and weight can be made to tell, it is absolutely certain that dangerous collisions must now and again occur. These dangers are more than of the game; they constitute the game and cannot be removed without alteration in the rules. But this is not all. Football is, in particular, dangerous in accordance with the spirit in which it is played. The element of personal conflict is very pronounced in either code and in the give and take of a scrimmage or *mêlée* loss of temper may lead to the infliction of serious injuries. We have pointed out these things before in very much the same words, and do not consider that we are taking up the position of milk-and-water alarmists. We know that we are expressing the views of many who can justly claim consideration as athletes when we express an opinion that it is no longer a sufficient reply to protest against the dangers of football to say that thousands play it. They do, and the fact makes the danger, if a small one, a very general one, and gives to the subject almost a national importance. We hope that those papers whose more especial province football, and the discussion of football, rightly is, will not consider the fact that we again call attention to the subject other than reasonable, and we hope that referees will punish with all possible rigour persons who play foully. A suggestion which we believe is not quite a new one has recently been referred to in the lay press—namely, that injured men in football matches should be replaced by fresh players. This may be regarded as a frank admission of the fact that unscrupulous players may be found amongst the large number of men who play the game—many of whom, moreover, play it for money—who are tempted by lust of victory to injure a player with the deliberate object of reducing the number of opponents. We can conceive that an organised system of substitutes in case of injury would much complicate the game, and we mention the suggestion not as advocating it (for it seems impracticable) but only as proving the confessed existence of foul players. While there should be general desire to minimise the risks of football to life and limb we most of all particularly desire to suppress dangerous foul play, and we look to the authorities of the game to punish in the severest manner—i.e., by heavy fines—clubs whose members are found guilty of the offence.

RECENT SANITARY CONGRESSES.

OUR columns have of late been so much occupied with the proceedings of various congresses that we have been obliged to forego the detailed reporting of others which have been given considerable prominence in the lay press. Amongst the most important of these were the annual conferences of the Sanitary Inspectors' Association which met last week at Liverpool and of the Incorporated Sanitary Association of Scotland which preceded it by a few days at Peebles. The Liverpool congress especially attracted conspicuous attention and the stimulating address of the President, Sir James Crichton-Browne, with its hopeful forecast of the ultimate triumph of sanitation over disease, formed the text of a considerable amount of appreciative editorial comment in the daily papers, the news columns of some of which printed full reports of his and other papers under such striking headlines as "Apostles of Sanitary Science." This we regard as a very healthy sign of the times, for the filling of many columns of prominent newspapers with accounts of debates upon sanitary matters proves the existence of an intelligent and growing public interest in the supreme laws of the people's safety. We need only allude to the topics upon which the militant sanitarian who presided at Liverpool based his address. Leaving the pursuit of his latest quarry, rats and vermin, he repeated the indictment of the common housefly as a habitual spreader of dirt and disease which he first brought against the ubiquitous insect when addressing a affected side, so as to establish communication with the external air, as I believe that an absolute collapse of the lung, which was not primarily present in either of my cases but which connexion with the external air by means of the cannula induced in Case 1, is productive of good.

Yelverton.

THE PREVENTION OF DEATHS UNDER ANÆSTHETICS.[1]

By FREDERIC W. HEWITT, M.V.O., M.A.,
M.D. CANTAB.,

ANÆSTHETIST TO H.M. THE KING; PHYSICIAN-ANÆSTHETIST TO
ST. GEORGE'S HOSPITAL; CONSULTING ANÆSTHETIST AND
EMERITUS LECTURER ON ANÆSTHETICS AT
THE LONDON HOSPITAL.

THE prevention of deaths during and after general anæsthesia constitutes one of the most pressing questions of the present day. As one of the objects of the British Association is "the removal of any disadvantages of a public kind which impede the progress of science," and as the author of the present paper is firmly convinced that the risks connected with anæsthetics would be very materially reduced by improving the conditions and circumstances under which they are now administered, it is hoped that the Association may help to solve this question by making some pronouncement in favour of the reforms herein suggested. Although we have no reliable statistics as to the death-rates under different anæsthetics, there is ample evidence, firstly, that a very large number of persons have died wholly or partly from the effects of these drugs; and, secondly (doubtless owing to the increasing number of surgical operations), that fatalities of this kind are increasing to an appalling extent.

In order that the risks incidental to generalised anæsthesia may be reduced it is obviously necessary in the first place carefully to consider the conditions and circumstances under which anæsthetics are now administered. At the present moment (1) the law permits any person whatsoever, whether he be medically qualified or not, to produce general anæsthesia for a surgical operation; (2) many of the examining bodies for medical qualifications permit their candidates to qualify without producing evidence of having received instruction in anæsthetics; (3) the departments of anæsthetics at our general hospitals are in many instances imperfectly and inadequately equipped, both in *personnel* and in other respects, the result being that the true principles of safe anæsthetisation are often barely, if at all, appreciated either by the teachers themselves or by their pupils; (4) in both hospital and private practice anæsthetics are frequently intrusted, even in the most difficult cases, to comparatively inexperienced practitioners who from no fault of their own find themselves incapable of successfully carrying out their responsible duties; and (5) with a few exceptions our hospitals publish no records as to the number and kinds of anæsthetics annually administered, so that any returns of deaths under anæsthetics, such as those of the Registrar-General of Births, Deaths, and Marriages, are useless as indicating either the relative risks of anæsthetics or the effects of any reforms upon death-rates.

It is hardly necessary to point out that if the public is to be protected properly the administration of anæsthetics must be placed upon a very different basis from that which at present exists. Experience has conclusively shown that though powerful poisons anæsthetics may be safely administered provided that those who undertake their administration have been properly educated and trained and that the principles under which they work and the methods which they employ are based upon scientific data. It would be beyond the scope of the present paper to enter fully into the strictly medical and scientific aspects of the problem of death prevention. It is contended that before such aspects can be profitably discussed the ground must be cleared by raising the level of this department of practice and by recognising the all-important fact that it is only by equipping all medical practitioners with increased knowledge and by applying it in practice that deaths under anæsthetics may be prevented. At the same time one cannot on such an occasion as the present refrain from acknowledging the valuable contributions to the subject which have been made by Professor A. Waller and other eminent physiologists, not only at previous meetings of this Association but elsewhere. Whilst fully appreciating the importance of their work and the fact that by regulating the percentage composition of anæsthetic atmospheres accidents may certainly be reduced in frequency, I am of opinion that before such methods can be adopted by medical practitioners and properly applied medical students must receive a better and wider education in anæsthetics than at present. They must be made fully to understand, in particular, the importance of free and absolutely unobstructed respiration; and when once the standard of education has thus been raised the strictly scientific work of the physiologist will yield a fruitful harvest. It is submitted that there is no single principle the faithful observance of which will insure safety in every case in which an anæsthetic is given. When we consider the different types of our subjects, the different operations which have to be performed, the different degrees of anæsthesia which may be required, the influences which different postures may have upon the circulation and respiration, and other essentially practical points, the truth of this proposition will become apparent. I would submit that there are three main principles which must collectively be observed in order to secure safe anæsthetisation. These are: (1) the selection of appropriate anæsthetics according to the exigencies of particular cases; (2) the adjustment of the vapour percentage of the anæsthetic to meet the varying requirements of each case; and (3) the avoidance of the slightest obstruction to the free entry and exit of air throughout the administration. Many distinguished authorities pin their faith to the *second* of these three principles, maintaining that by the regulation of the percentage composition of anæsthetic atmospheres dangerous conditions may invariably be avoided. This view I find myself unable to accept. Were it practicable in the human subject to introduce anæsthetic gases and vapours below the glottis and thus to eliminate the various forms of obstructed breathing which so often complicate and render fatal the anæsthesia of surgical practice, the administration of chloroform and other agents might undoubtedly be made as safe in the operating theatre as Professor Waller has demonstrated it can be made in the physiological laboratory. But such a system is unfortunately inapplicable, and I submit that unless it can be demonstrated that there is just as free a lung ventilation when a 1 per cent. or 2 per cent. chloroform vapour is administered to human subjects through the naso-oral channels as there is when a similar percentage mixture is administered to lower animals through tracheal cannulæ, it is illogical to argue from the latter to the former subject. It would be exceedingly interesting and of great importance in solving the main question if arrangements could be made whereby a small committee of physiologists might see for themselves the manner in which anæsthetic difficulties and dangers generally come about in surgical practice. I am of opinion that such a committee would soon realise the great differences which exist between naso-oral and tracheal anæsthetisation and the marked influence which the asphyxial factor incidental to human anæsthetisation has in modifying and complicating the usual phenomena of anæsthesia. In the meantime I would urge that unless the other two principles above mentioned be applied in conducting all administrations success cannot be invariably depended upon. I am inclined, indeed, to regard the third, or last-mentioned, principle as the most important of the three, for my whole clinical experience and the examination of the records of a large number of recent fatal cases (which by the kindness of Dr. F. J. Waldo and of Dr. L. Freyberger have been placed at my disposal) convince me that in the great majority of deaths under anæsthetics some obstruction to breathing above the trachea has been a powerful factor.

I contend that the above considerations point to the urgent necessity for higher education and skill amongst those to whom the important duty is intrusted of maintaining adequate anæsthesia for surgical operations. The first reform should be to make it a penal offence for anyone but a legally qualified medical practitioner to administer an anæsthetic. The second should be to improve and extend the anæsthetic departments of our hospitals by appointing experienced men of the highest professional and academic attainments to the various offices of such departments, so that all anæsthetics shall be administered or supervised by such but instead of appointing Dr. J. W. Mackenzie, the junior assistant, to the fifth acting membership, the managers passed him over and appointed Dr. Mackay, who has thus fallen from his high estate of senior acting member to that of junior acting member. The new rule is naturally objected to, not only by the whole of the medical staff except Dr. Mackay, but also apparently by other medical men in the town. Formerly, it will be seen, the assistant members of the medical staff were practically sure of promotion, but under the new rule they are by no means so. The staff has, we hear, lodged a protest. We would remind the managers that an infirmary can get on without managers but that it cannot get on without medical men.

PERNICIOUS ANÆMIA IN TUBERCULOSIS.

AT a meeting of the Société Médicale des Hôpitaux of Paris on June 19th M. Marcel Labbé and M. Agasse-Lafont reported a case in which pernicious anæmia was due to tuberculosis—a very rare condition. A married woman, aged 36 years, was admitted into hospital on April 27th, 1908, for œdema, anorexia, fever, and great weakness. She had never been pregnant and had enjoyed good health until two years previously when she began to develop anæmia and to lose strength. After some months megrim, vomiting, and diarrhœa supervened. On admission she was extremely weak. The skin was very pale and the mucous membranes were completely decolourised. There was general œdema which was more marked in the lower limbs. Examination of the blood showed the changes characteristic of pernicious anæmia. The red corpuscles were reduced to 380,000 and were of very unequal size. Their hæmoglobin value was 1·85. Poikilocytosis and polychromatophilia were well marked. There were from two to four nucleated red corpuscles to every 100 leucocytes. The latter numbered from 2500 to 3600 and were almost normal in kind except for the presence of 5 per cent. of myelocytes. The fæces were yellow and did not contain any parasites. The abdomen was very tense and œdematous and showed a collateral circulation. The liver was large, extending two or three fingers' breadth below the ribs. The spleen appeared to be normal. In the chest bronchial breathing at both apexes and bronchitic râles were heard. There was abundant foamy sputum which did not contain the tubercle bacillus. The temperature varied from 102·3° to 103·1° F., being highest in the evenings. The pulse was from 120 to 130 and feeble; the heart was slightly dilated. There was slight albuminuria. Though the blood examination showed the presence of pernicious anæmia the temperature pointed to an infection. Cultures made from the blood remained sterile. The pulmonary signs pointed to tuberculosis but the absence of the bacillus from the sputum prevented this from being diagnosed. The fresh marrow of the calf, saline injections, and oxygen inhalations were prescribed. The diet consisted of a litre of milk, the yelks of one or two eggs, and some grammes of raw meat daily. The state of the blood improved slightly and on May 13th the red corpuscles numbered 520,000, but the other symptoms did not improve and the patient grew weaker and died on May 26th. At the necropsy all the organs were found decolourised. There was some citrin fluid in the pleural cavities and the bases of the lungs were united to the diaphragm by recent soft adhesions. The bronchi contained pus. The apex of the left lung was congested and greyish at certain points. The lower lobe of the right lung was very œdematous and showed on its surface fine granulations and in its interior a little caseous tubercle. The tracheobronchial glands formed a voluminous mass and several of them were indurated or caseous. Attempts to find the tubercle bacillus in sections of the lungs and glands proved negative. The peritoneal cavity contained from three to four litres of sero-fibrinous fluid. The great omentum contained small, semi-transparent granulations of tuberculous appearance. The liver showed fatty degeneration of all its cells and peri- and intra-lobular sclerosis and masses of round cells suggesting young tubercles. The bone marrow in some places showed a myeloid reaction. The principal point of interest is the relation of the pernicious anæmia to the tuberculosis. Was the latter grafted on the former, as it sometimes is in leukæmia, or was it the cause of the former? The first hypothesis is negatived by the fact that the tuberculous lesions were old. A moderate degree of anæmia occurs in almost all cases of tuberculosis and is well recognised, but forms of anæmia which dominate the clinical picture are not well known, though they are more frequent than has been supposed. The slightest and the most frequent form of anæmia in tuberculosis is of the chlorotic type; the most severe and the most uncommon is of the type of pernicious anæmia. Between these two are intermediate forms. Only a few cases of the type of pernicious anæmia have been reported. Paul and Rivet have recorded a case of chronic pulmonary tuberculosis in a woman, aged 41 years, in which anæmia supervened. The red corpuscles numbered 488,000 and the blood contained normoblasts, myelocytes, and hæmatoblasts. The necropsy showed pulmonary tuberculosis, fatty degeneration of the liver, and a feeble myeloid reaction of the spleen and marrow.

THE MATHEMATICS OF PRESCRIBING.

A CONTRIBUTOR to the *Chemist and Druggist* has drawn attention to an interesting account in Sprengel's "History of Medicine," published about a hundred years ago, of a unique method of prescribing worked out by Jacob-Ebn-Izhak-Alkhendi, who lived in Bagdad in the ninth century. Sprengel obtained the particulars from Alkhendi's work on the "Degrees of Compound Medicaments." Alkhendi was a mathematician as well as a physician and he based his theory of prescribing on Galen's doctrine of hot and cold, humid and dry drugs. He formulated the equation $x = b^{n-1}a$, and explained it thus: a is the first degree, b the last, x the exponent, and n the number of terms. In applying the equation to remedies the following explanation is given: "The first degree results from the multiplication of an equal mixture by two; the second of that of the total of the first degree by two; and the third of that of the second degree by two. Thus, the total of the second degree is the quadruple of the equal mixture and that of the third eight times stronger than that mixture. The total of the fourth degree is equal to the uniform mixture in the sixteenth quality, and to the first degree in the eighth quality." In case this explanation is not clear an example is given of one of Alkhendi's prescriptions:—

	Hot.	Cold.	Humid.	Dry.
Cardamoms, 1 drachm	1	½	½	1
Sugar, 2 drachms	2	1	1	2
Indigo, 1 drachm	½	1	½	1
Myrobalans, 2 drachms	1	2	1	2
	4½	4½	3	6

"This compound medicine," it is explained by Sprengel, "is exactly balanced as regards heat and cold, but the dry qualities being double the humid ones, the mixture is dry in the first degree. If the total had been twelve of the dry to three of the humid, the mixture would have been dry in the second degree. Let it be remembered that these hot and cold, wet and dry medicaments of the first, second, third, and fourth degrees had to balance cold and hot, dry and wet, diseases of the same number of degrees, and that medicines adapted for one part of the body were rather rigorously not permitted to trespass on the domain of those applicable to another part. ...... The theory of degrees but was otherwise healthy with clean valves. The aorta showed one or two tiny patches of atheroma near the aortic valves. The liver was large and friable. The spleen was soft. The kidneys showed rather adherent capsules, especially the right one, with stellate veins, striate cortices, and ill-defined pyramids; they were very red and tough but there were no granulations. There was no sign of injury to the kidneys from the accident. The appendix was long, thin, curved, and bound down in nearly all its length; there were several fine band-like adhesions holding it near its tip. The second, third, fourth, and fifth ribs were fractured at about 1 inch to 1½ inches from the costo-chondral junction; they showed no displacement. The sixth and seventh ribs were fractured about 1½ inches from the side of the spinal column; they had evidently been displaceable into the chest and may have been responsible for the tear in the lung. The first and other ribs escaped fracture. The skull and brain were not examined.

Muttaburra, Queensland.

THE PATHOGENESIS OF TABES DORSALIS.

By TOM A. WILLIAMS, M.B., C.M. EDIN.

CONTROVERSY as to the pathogeny of tabes has not ceased since Duchenne[1] surmised its sympathetic origin and Charcot[2] later supposed it to be a posterior column dystrophy, similar to that of Friedreich's ataxia. His great authority prevented due attention to the researches of Obersteiner and his followers until the memoir of Redlich appeared in 1896.[3] The discoveries as to the syphilitic etiology of tabes caused greater attention to the work of Nageotte,[4] who in 1894 had indicated the constancy of lesions on the radicular nerve at the point where it receives its meningeal sheaths. These lesions correspond to one or other stages of the granulomatous process, varying as they do from simple round-cell infiltration to granuloma, and even breaking down with formation of cavities. They are due to primary chronic meningitis, evidenced by the lymphocytosis found by spinal puncture during life and post mortem when skilfully looked for, although the tendency of the process to resolution and fibrous-tissue formation leaves only a slight thickening in the membrane, already fibrous by nature.

The changes in the cord are consecutive to this. That this is so is proved by similar changes of the posterior column after disease of, or experimental section of, individual roots[5] and by the changes occurring in the mechanical affection of the radicular nerves due to the increased intraspinal pressure caused by the growth of cerebral tumours.[6] The noxa falls upon the root fasciculi very disparately[7] and this corresponds to the disparate nature of the sensory troubles, which do not preponderate so much as formerly supposed upon the fibres which subserve the sense of attitudes and of muscular movement; for it is now definitely shown that cutaneous sensations are always involved more or less, though probably later in the disease.[8] The superficial lightning pains described by Gowers[9] and the psychometric analysis of the sensibility of tabetics by Vaschide[10] are an index to this, while the researches of Head[11] enable us to explain the modifications in terms of deep, protopathic, and epicritic sensibility. The fibres subserving the life of internal relation may differ morphologically from those subserving external relationship as contended by Pierre Bonnier[12] with particular reference to the eighth nerve, the principal posterior root, where the cochlear portion whose function concerns the outside world is affected only rarely, while the vestibular portion is concerned with intrinsic relationships and is involved very commonly indeed in the tabetic process. However this may be, it is certain that impaired sense of attitudes is always accompanied by *impairment of the deep pain sense* and of perception of the vibrations of the tuning fork by the bones,[13] and as these functions are conveyed in the same peripheral path while they are separated within the cord[14] clinical evidence is in entire harmony with the pathogenetic theory advanced by Nageotte. The data furnished by the optic nerve symptoms are *similarly best explicable* by a meningeal affection, involving in this case not a posterior root but a homologue of an intraspinal path.[15]

The tabetic symptoms referable to the sympathetic do not differ from those produced by experimental section of the spinal roots, nor from those in syringomyelia, which, however, attacks the cell bodies in the intermedio-lateral column.[16] Charcot's negation of changes in the sympathetic is effectively disproved by the researches of Roux,[17] who found the medullated fibres markedly decreased in tabetics. The anterior roots are not unaffected, but the relative absence of serious myopathies early in the disease is accounted for by the rapid regeneration of the fibres. This is shown by the "*terminaisons en croissance*" exhibited by Nageotte's[18] preparations and by the results of section experiments.[19] The regeneration of the posterior root fibres extends only to Redlich's ring at which they lose the neurilemma sheath.[20] Finally, evanescent lymphocytosis and reflex iridoplegia, the two most characteristic signs of tabes, are found in many cases of syphilis without other tabetic symptoms[21]; indeed, both sometimes occur in the secondary stage, the former in as many as 40 per cent.[22] The contention of Babinski and Nageotte[23] is therefore accepted that a chronic syphilitic meningitis is responsible for what has been called tabes dorsalis and that it was formerly disregarded on account of the tendency to the occurrence of resolution and fibrosis of the lesions.

The practical application of this conclusion may be of the greatest importance in the treatment of the disease. Cases taken early may be completely arrested,[24] and in all cases the active manifestations may be resolved if adequately treated before the destruction of the noble elements has occurred, though naturally the residues of former exacerbations cannot be removed.

A MODIFICATION OF THE ROMANOWSKY STAIN.

By F. H. JOSEPH,
ASSISTANT BACTERIOLOGIST.

(*From the Government Laboratories, Johannesburg, South Africa.*)

THE following quick and simple method of preparing an eosin-methylene blue compound stain gives excellent results. The appearances of blood films stained by this method are similar to those coloured by Leishman's stain, although the blue and violet tints are a little different and the red is deeper. The nuclear structure is particularly sharply defined and the granules of the various leucocytes are well shown. The stain has now been in constant use in these laboratories for 18 months, and in our hands has given better and more uniform results than Leishman's stain.

Solution I., Polychrome methylene blue.—Dissolve 1 gramme of Grubler's ordinary methylene blue in 100 cubic centimetres of distilled water. After 24 hours decant the supernatant fluid, and to 90 cubic centimetres add 10 cubic centimetres of a 1 per cent. aqueous solution of sodium straining at stool found five metres of small intestine protruding from the anus. Professor Adelmann mentions a case seen by Pyle where a young woman who had been kicked and thrown down experienced great difficulty the next time she went to stool, and after violent straining forced out a mass of small intestine and a large quantity of blood. She died shortly afterwards and at the necropsy the abdominal organs were found considerably displaced, the mass protruding through an extensive wound in the posterior wall of the rectum consisting of part of the cæcum and nearly the whole of the jejunum. Roché[1] actually saw a woman who had previously consulted him for a vesico-vaginal fistula pass through a prolapsed rectum a mass of small intestine while he was examining her. Two cases of female children where wounds of the rectum were produced by an enema tube and a fall on a broken chair respectively were mentioned in a clinical lecture delivered by Mr. G. H. Makins at St. Thomas's Hospital,[2] but no protrusion of the small intestine occurred in either. Stuthgard of Copenhagen saw a man who with the idea of curing excessive constipation had pushed a pole into his rectum so as to cause perforation. Dr. J. B. Neal has recorded[3] the case of a woman in the Wandsworth and Clapham Infirmary who seems to have been thrown on her face, a small cucumber having then been forced up her rectum, the anterior wall of which was torn half across 3½ inches from the anus. It has been found by experiment that violence of this kind caused rupture into Douglas's pouch if the body was prone but that the force impinged against the sacrum if it was supine.

RECENT SUMMER DIARRHŒA IN ENGLISH TOWNS.

THERE are few features of urban mortality that have received from sanitary experts more studious attention than the annual recurrence, with varying intensity, of infantile summer diarrhœa, and yet no satisfactory measures for its control and abatement have yet been devised. During the recent early summer the rate of mortality in the 76 large English towns, dealt with in the Registrar-General's weekly returns, was unprecedentedly low, but during August the death-rate showed a very marked increase. The deaths registered in these towns during the four weeks ending the 29th of last month exceeded by no less than 4012 the average mortality recorded in the preceding five weeks of July, of which increase 938 occurred in London and 3074 in the 75 towns outside the metropolis. Of this marked excess of deaths in the 76 towns during August, 3138 were deaths of infants under one year of age, of which 728 were recorded in London and 2410 in the 75 towns outside London. During the five weeks ending August 1st, the average weekly number of deaths in the 76 towns attributed to diarrhœa did not exceed 166, whereas in the succeeding four weeks ending August 29th the weekly average increased to 923; the aggregate excess in the number of fatal cases of this disease during the four weeks was 3026, of which 670 occurred in London and 2356 in the 75 provincial towns. It may be noted that of the 810 deaths in London referred to diarrhœa in the four weeks of August, 625 were of infants under one year of age and 159 of children aged between one and five years; thus only 26 of the 810 deaths from this cause occurred among persons aged above five years. It may, moreover, be fairly assumed that practically the whole of the marked increase of mortality during August occurred among young children under five years of age, since of the recorded increase in London at all ages and from all causes (938) 905 were deaths of children under this age. In view of the admittedly intimate connexion between the mortality from summer diarrhœa and temperature and rainfall the meteorological conditions prevailing during the past two months are not without interest. The mean temperature of the air at Greenwich during the five weeks ending August 1st was 62·1° F. and 0·4° below the average in 65 years, and 3·66 inches of rain were measured on 12 days. During the four weeks ending August 29th the mean temperature did not exceed 59·8° and was 2·0° below the average, and 2·89 inches of rain were measured also on 12 days. The mean temperature in July, therefore, differed but slightly from the average, while that in August was distinctly below the average, and the rainfall somewhat exceeded the average in each month. The marked increase in the fatality of diarrhœa among children during August can therefore scarcely be attributed to meteorological conditions, as the mean temperature was considerably lower than in July. Still more difficult to explain are the startling variations in the fatality of this disease in different towns, unless they be attributed to varying degrees of ignorance and neglect in the care and treatment of infants. In the seven weeks ending Sept. 5th, for instance, 178 deaths resulted from diarrhœa in the South Wales mining district of Rhondda, against but 62 in Cardiff, which has a much larger and more distinctly urban population. The marked difference between the mean rates of mortality from diarrhœa in Lancashire and Yorkshire manufacturing towns has, moreover, never been satisfactorily explained.

A TELEGRAM from the governor of Mauritius received at the Colonial Office on Sept 11th states that 2 cases of plague were notified for the week ending on that date and that there were 2 deaths from the disease. The Department of Public Health of Queensland, in a bulletin dated August 8th, states that for the week ending on that date one case of plague was reported—namely, a man, aged 50 years.

WE regret to announce the death, at the early age of 41 years, of Mr. Edward Percy Paton, the dean of the Medical School of the Westminster Hospital. Mr. Paton, Mr. H. L. Barnard, and Dr. Bertram Abrahams were three of the best known of the younger men attached to the great metropolitan hospitals and their loss will be severely felt.

REPORT OF THE ROYAL COMMISSION ON THE FEEBLE-MINDED.

I.

THE report commences with a consideration of the Poor-law and its effects upon the condition of the mentally defective in towns and in the country, apart from the metropolis. An investigator of the Commission writing of certain northern unions, reports that there the majority of the mentally affected persons met with in the Poor-law institutions are sufficiently looked after though their condition can by no means be regarded as satisfactory. "They are perfectly free to leave the workhouse at will, and when it is borne in mind how many young women, who have already had illegitimate children, there are amongst them, it will be recognised what grave risk there is, in both sexes, of the further propagation of their defects. The occupation of those who are in the workhouse is also capable of radical improvement; many of them could do, under efficient supervision, a certain amount of useful work, which would make them more serviceable members of society than they are at present in enforced idleness or doing only the roughest or most unskilled work." Of the classes of feeble-minded persons there are several. There are those either born in the workhouse and who are nearly always illegitimate, or who enter at a very early age owing to the death of the contain considerable information, and there is a brief allusion to the fact that certain neuroses are associated with deafness characterised by a great loss of bone conduction. In Chapter XLVII. labyrinthine suppuration, combined with caries and necrosis, is described, and Chapter XLVIII. briefly discusses deaf-mutism and the means of dealing with deaf-mutes.

[2] THE LANCET, Oct. 28th, 1899, p. 1145.
[3] THE LANCET, Feb. 4th, 1882, p 182.

The writing and illustration of the book are excellent. We have been critical in the above review out of regard for the size of the task which the author has essayed. If he has not been completely successful he has, at any rate, given us a very good book.

International Clinics. Edited by W. T. LONGCOPE, M.D., Philadelphia; U.S.A. Vol. IV., Seventeenth Series. 1907. London and Philadelphia: J. B. Lippincott Co. Pp. 308.

SEVERAL interesting contributions will be found in this volume dealing with various branches of medical science. Dr. A. S. Warthin, professor of pathology in the University of Michigan, makes a suggestive comparison between the value of Roentgen irradiation and the administration of arsenic in the treatment of leukæmia. After an analysis of over 200 cases of leukæmia treated by Roentgen irradiation he arrives at the following conclusions. There is no positive proof of an absolute cure of leukæmia by this method of treatment, although a symptomatic cure occurs with remarkable frequency. Not all cases, however, respond to the treatment, even after "extended irradiation," but the earlier in the course of the disease the exposure to the rays is begun the more pronounced is the reaction of improvement. In all of the cases recurrence of symptoms eventually takes place and the fatal termination of the disease has in no case been averted. It is apparent, however, that the fatal issue is postponed and many of the patients have gained an extension of life varying from several months to one or two years. With regard to the use of arsenic, temporary improvement is also produced, but a fairly large number of cases do not respond to the drug, and, further, since the good effect of arsenic can only be obtained by pushing the drug to the limits of tolerance and continuing it indefinitely, it follows that the danger of arsenical poisoning must be considered. After reviewing the whole of the evidence Dr. Warthin is of opinion that a combination of the two methods of treatment affords the best means of delaying the fatal issue of leukæmia. A careful and systematic examination of the patient's blood should be frequently made. An increasing diminution of the red cells is an indication for pushing the arsenic, while an increase in the number of white cells or a change in the proportion is a signal for renewing the irradiation.

Another article that will well repay perusal is by Dr. H. K. Pancoast, lecturer on skiagraphy, University of Pennsylvania, entitled "A Study of Gastroptosis from the Radiographic Standpoint." By means of numerous diagrams the various types of gastroptosis are well shown. This is a subject upon which definite knowledge has hitherto been wanting, and this paper denotes a valuable advance in the demonstration of the abnormalities which may occur. Professor G. Calmette writes on the Ophthalmo-Reaction to Tuberculin. He maintains that this test enables the practitioner "to reach with almost absolute certainty a diagnosis in various forms of tuberculosis when clinical and bacteriological examination fails to give a definite result."

Amongst other contributions to this volume are a Report of Cases of Perforation in Typhoid Fever Operated Upon at the Pennsylvania Hospital, by Dr. C. T. Mitchell, surgeon to the out-patient department of the Pennsylvania Hospital; Immunity and Vulnerability, by Dr. C. D. Palmer, emeritus professor of obstetrics and gynæcology, medical department of Cincinnati University; Right-angled Contraction of the Tendon Achillis as a Cause of Stumbling and Halting in Children, by Mr. A. H. Tubby; and Disorders of Sleep, by Dr. Purves Stewart.

The various numbers of "The International Clinics" generally contain many valuable papers, and the volume now before us well maintains the standard which characterises its predecessors.

A Manual for Midwives. By C. J. NEPEAN LONGRIDGE, M.D. Vict., F.R.C.S. Eng., M.R.C.P. Lond., Pathologist and Registrar, late Resident Medical Officer, at Queen Charlotte's Hospital; Examiner to the Central Midwives Board, and Lecturer on Midwifery for the London County Council. London: J. and A. Churchill. 1908. Pp. 309. Price 3s. 6d. net.

IN this book designed for midwives Dr. Longridge has tried to write each sentence in such a way that it could not be misunderstood, and certainly we can congratulate him on the success with which he has carried out this endeavour. Of the many and various works which have been written for midwives during late years this is one of the simplest and the best. Dr. Longridge has had drawings made from specimens in the Museum of the Royal College of Surgeons of England of the pregnant uterus and thus he is able to refer his reader to the actual specimen itself if she is so fortunate as to be carrying out her studies in London. The ritual of the method of making a vaginal examination looks a little complex on first reading it, but this is an error, if error it be, on the right side, since over-elaboration of detail is not likely to do any harm and may well serve to impress the midwife, who perhaps is already in practice, when she contrasts what she possibly does in such a case with what the author tells her she should do. It is a pity that Dr. Longridge thinks it necessary to recommend the use of two antiseptic solutions—namely, lysol and perchloride of mercury—but we quite agree with him when he calls attention to the disadvantages of swabbing the vulva with a solution of the latter. The value of the book is increased by the addition of the rules of the Central Midwives Board, a short chapter on the early symptoms of cancer (an excusable digression in view of the importance of the subject), and a section on advice to mothers on the care of their children, published by the authorities of Queen Charlotte's Hospital. Altogether this is a most excellent manual highly to be commended.

Traité Pratique de Thérapeutique Infantile Médico-Chirurgicale. By Dr. PAUL LE GENDRE and Dr. AUG. BROCA. Second edition. Paris: G. Steinheil. 1908. Pp. 759. Price 15 francs.

THIS work, written by a physician and a surgeon, is a very complete manual of the treatment of children's diseases. It opens with a brief introductory consideration of the special features presented by disease in children and of the importance of feeding and other general measures as *opposed to* drug treatment. The first chapter then deals with infant feeding, and we are glad to find that *no* complicated methods of percentage feeding are commended. The second chapter is devoted to the child's surroundings—light, warmth, ventilation, and so on—as well as to general therapeutic measures, such as hydrotherapy, massage, and gymnastics. In the third chapter are discussed "general therapeutic indications," in which are included procedures such as purgation, sweating, diuresis, and so forth, the use of tonics, hypnotics, and antipyretics, the general hygiene of the sick room, serum treatment, and the notification of infectious diseases. In the fourth chapter methods of administration of remedies and the dosage suitable for class of children, receives the children into its classes between the ages of five and 16, but at the latter age no provision for them is forthcoming, however defective they may be. Even such accommodation as was designed for imbeciles has been diverted to other purposes and boards of guardians have to a large extent adopted the practice of sending to institutions primarily intended for imbeciles their old men and women suffering from senile decay. Indeed, as Sir John McDougall said in his evidence, "there is no line between a lunatic and an imbecile of later age except that a very tiresome imbecile is a lunatic, while a very quiet lunatic is an imbecile—that is the practical result." The general conclusion of the Commission on the subject is that there are in London a division of authority and a want of administrative accord which are fatal to any successful treatment of the problem.

It is unfortunately only too frequently the case that the public regard conditions of mental defect as irrecoverable. In this, yet more unfortunately, they are abetted by medical men. The methods of Séguin, Bourneville, and others have received but scant attention, and of what can be done for mentally defective children we are for the most part in lamentable ignorance. It is therefore well to lay stress upon the evidence on this point collected by the Royal Commission. Miss Turner, a medical witness, gave evidence to the effect that there might be total recoveries if proper treatment and education could be commenced at a sufficiently early age. "Five is really too old to start special training; three would be better." Miss Hargreaves, matron at Rochester House, showed how imbeciles could be educated into supervised forms of occupation, and the method by which this result was obtained is now adopted on a larger scale at Darenth Industrial Colony. Dr. A. Rotherham said: "The children could be very greatly improved; they could do anything mechanical so long as they were looked after." Parallel to this evidence that the condition of mentally defective children is capable of great improvement is evidence of the deterioration of such children as are withdrawn from supervision and instruction.

In the forefront of the Royal Commission's recommendations a problem is set out which appears to us to be of so great importance that we quote the paragraph *in extenso* :—

> Before coming to a conclusion on the alternative, whether the Poor-law system should be expanded so that it may make entire provision for mentally defective persons, or whether this task should be assigned to some other control and local authorities, the ultimate question, which both parties raise, and which we have to decide, is whether the mentally defective should be considered and dealt with as suffering primarily from mental disease, or primarily from poverty or destitution, however caused? In the former case they would be relieved—whether paupers, or prisoners, or inebriates, or "feeble-minded," or persons of "unsound mind," as having a claim on the community on the common ground that they are mentally afflicted; and assistance for them would be organised with a view to their treatment as patients. In the latter case they would be relieved as poor or destitute persons who happen to be mentally defective, and who on that account are paupers as being in need of relief, but incidentally patients, as being in special need of treatment. But the evidence shows that the division between pauper and non-pauper is quite unreal in the case of the mentally defective. The son of respectable parents, who is permanently supported wholly or in part by relatives or friends, requires, as mentally defective, the same treatment as another person whose relatives and friends cannot help him at all; and the greater or lesser possibility of obtaining payment for the treatment—the more or less poverty or destitution—is not the dividing line in these cases, but the existence or non-existence of mental disease. Further, the distinction, on which we insist, is especially applicable to a class of case for which it would be difficult for the great mass of people to make any provision. These cases, wherever they may be, or whatever public department or organisation may deal with them, involve continuous expenditure greater than can ordinarily be met by the people themselves, even when they are capable and industrious members of the middle and working classes. ...... All possible obligations which can reasonably be imposed should, indeed, in our opinion, be enforced on relatives, and the help of friends and voluntary agencies also should be used to the utmost. But in the development of any organisation for the care of the mentally defective the precedent of the Lunacy Acts should, we think, be followed, rather than the precedent of the Poor-law. Under the Lunacy Acts intervention is due to the existence of mental incapacity; under the Poor-law to the existence of poverty and destitution. It must also be remembered that the certification, detention, and segregation, in regard to which all our witnesses are agreed, are advocated in the interest of the community at large and not merely or chiefly, as relief is given under the Poor-law, in order to meet the personal needs of particular cases.

So far as segregation is concerned there is a general consensus that it is not good for the individual or for the community that a person who is mentally defective and has been convicted of crime should be set free, like an ordinary prisoner, to go where he may on discharge. Equally is this so in the case of inebriates, or paupers, or children of school age, who are mentally deficient. Dr. James Kerr, the medical officer of the London County Council, states of the kind of children handled in special classes: "Many who can contribute materially to their own livelihood would be better if under custodial treatment. ...... Compulsory powers for detention will be required for many cases. ...... The matter as a State provision for the improvement of social conditions will be almost futile, if provision is not also made for continuing the custodial treatment after school ages." To improve the condition and meet the needs of the mentally defective, whether in elementary schools, prisons, inebriate homes, or asylums, the Commission considers that it will be necessary that there should be established one central authority for the general supervision of such persons and to regulate the provisions made for their maintenance, care, treatment, and training. The local authority which is to carry out such regulations, it is suggested, should be the council of each county or county borough. The Commission finds nothing peculiar in the conditions which obtain in London which would suggest a scheme different from that recommended for England generally, and since it is of opinion that a Poor-law authority cannot suitably undertake the care of the mentally defective it is unable to recommend that the Metropolitan Asylums Board should be the local authority in London, but it is suggested that the duty should devolve upon the County Council acting through a statutory committee. As regards the education of mentally defective children it is recommended that where there are special classes they should be used for teaching those who would be able to look after themselves later in life and that such classes should pass under the Board of Control and should not remain under the Board of Education. To ascertain the number of mentally defective children and to provide for their education, supervision, and segregation it is recommended that the system of registration now in force with regard to school children should be turned to account and made the foundation of records which would be of use in caring for them throughout life. It is recommended that notification from public authorities and private homes should be required by statute, but that otherwise there should be no notification except in regard to patients received for profit. Where there are no special classes or schools it is recommended that the local authority may intervene and either make provision in connexion with the education authority or independent of it. The Commission is of opinion that the ordinary education authority should not be the authority in charge of mentally defective children. To the Commission it seems that a single and continuous control over the mentally defective person, both in childhood and subsequently in adult life, is indispensable and that the education authority as the educator of children and not as the supervisor of adults could not exercise this control, and just as the Poor-law, established for the care of the poor and destitute, is unsuitable for the care of the mentally defective, so the educational system of the country, established for the teaching of the normal child, is unsuitable for the child who can never reach the mental level of the normal.

OPENING OF THE LONDON MEDICAL SCHOOLS.

Winter Session 1908-09.

St. Bartholomew's Hospital.—The session will begin on Oct. 1st. The old students' dinner will be held on the same evening in the great hall of the hospital at 7 P.M., when Mr. H. Gilbert Barling will preside.

Charing Cross Hospital.—The session will commence on Oct. 1st by the delivery of the seventh biennial Huxley lecture on Recent Advances in Science and their Bearing on Medicine and Surgery, in the out-patients' hall at the hospital, at 4 P.M., by Sir Patrick Manson, K.C.M.G., F.R.S. The dinner of the past and present students will take place on the evening of the same day, at 7.30 P.M., at the Criterion Restaurant, when Mr. Edgar A. Browne of Liverpool will preside.

St. George's Hospital.—The session will open on Oct. 1st with an inaugural lecture which will be given by Dr. Charles Slater at 4 P.M. The annual dinner will be held on the same evening.

Guy's Hospital.—The annual dinner and first meeting of the Guy's Hospital Physical Society will be held on Oct. 8th.

helpful. No doubt this little work will prove useful to those who are unable to consult the larger text-books upon the subject. It is a pity that so many errors in the spelling of proper names should have been left uncorrected.

First-Aid to Medical Treatment of Tamils and Singhalese, for the Use of Tea and Rubber Planters and Estate Dispensers. By R. J. DRUMMOND, M.D. Edin. Lindula: Walker and Greig. 1908. Pp. 58.—The author of this book has undertaken what is always a difficult task, that of supplying a medical guide for the use of non-medical persons in places where professional aid is unattainable. He disclaims any desire to let his book "compete with, or be a substitute for, the medical service that the Government have inaugurated in Ceylon," and rests the sanction for it in irrefutable words: "Every experienced tea-planter knows that a neglected 'cold' often leads to pneumonia and death; that a neglected diarrhœa often ends in dysentery and death; and that a neglected sore often ends in blood-poisoning and death." Dr. Drummond has not always quite hit the happy mean between teaching too much and teaching too little. In the opening section on Malaria, for instance, he describes a course of treatment extending over six weeks, including prescriptions containing arsenic, iron, and strychnine. Surely such after-treatment appertains rather to the medical officer than to the lay minister of first-aid. Nor would the latter profit much by reading of bronchitis: "If a stethoscope be applied to the chest the noise in the lung will be like a bellows blowing or the crackling sound of a distant fire on grass patnas." However, the book contains a trustworthy and useful symptomatology and guide to treatment of the commoner diseases written in plain language, although it must be confessed in terribly slipshod grammar. The treatment of cholera and dysentery is very thoroughly described in what are perhaps the best sections in the book. There is a very brief account of surgical first-aid; and an interesting section, headed "Medico-Legal," on native poisoning practices and caste punishments, which includes a terrible account of infanticide, "a very common crime in Ceylon," affords a startling criticism on the protection afforded by the British Raj to the caste-ridden native. Dr. Drummond's little book should command a wide circulation in the Ceylon tea-gardens, and in intelligent hands will prove of considerable utility. The preface shows it to have been written in response to a request for such a work from those to whom it is addressed.

JOURNALS AND MAGAZINES.

Annals of Tropical Medicine and Parasitology, University of Liverpool. Vol. I., No. 4. Illustrated. London: Williams and Norgate. Pp. 71. Price 7*s* 6*d.* net.—The investigation and suggestions for preventing the so-called "Canary fever," by Mr. C. E. Walker, form the first paper in this number. We have already printed an abstract of it in THE LANCET of June 13th, p 1707. An interesting study of a somewhat rare disease caused by a parasitic worm, "porocephalus moniliformis," by Dr. A. Broden and Dr. J. Rodhain from the Leopoldville Laboratory in the Congo Free State, is contained in the second paper. The patient whose case is described showed extreme tenderness in the left hypochondriac region and parts of the epigastrium. The liver was not enlarged, but there was some slight engorgement of the base of the left lung. He was extremely constipated and vomited a certain amount of blood. After about four weeks' illness he died quite suddenly. The intestine and peritoneal cavity were full of some long bacilli which were anaerobic but which have not been identified. Only one larva of the worm was found, but many hæmorrhagic patches and pockets were found in the small intestine. A detailed description of the worm is given. Mr. Robert Newstead contributes a paper on the Habits, Life-Cycle, and Breeding Places of the Common House Fly. The results of the investigations described should prove very valuable, both from an economic and a scientific standpoint. The chief breeding places of the house fly apparently are—middensteads containing horse manure only; middensteads containing spent hops; and ashpits containing fermented material. Mr. Newstead found that in stable-yards where poultry were kept and allowed to wander about freely flies were kept under to a very great extent, and that while both open and closed ashpits were infested with the larvæ the flies gave preference to the closed receptacles. The non-breeding places were—middens containing excessively moist and non-fermented cow-dung; patent ash-bins; refuse in ashpits saturated with water; and human excreta lying in courts and passages. After dealing with the life-cycle of the common house fly the author summarises his observations as follows: That covered ashpits and middens were as badly infested as those which were open. That house flies breed in all temporary collections of fermenting matter. That house flies breed in relatively small numbers in ashpits where no fermentation takes place. That they do not breed in ashpits which are emptied at short intervals or in the patent bins. That the use of disinfectants in ashpits does not prevent the flies breeding in such receptacles. That very dry or excessively wet ashes or moist cow-dung does not harbour them. That the life-cycle of the fly in all kinds of fermenting materials is reduced to the minimum period of from 10 to 14 days, and that in the absence of such artificial heat the cycle may occupy a period of from three to five weeks or more, according to the temperature of the outside air. That house flies do not depend entirely upon excessively warm weather for breeding purposes, though in hot seasons they would breed much more rapidly in non-fermenting materials and their numbers under such conditions would be greatly increased. He makes various suggestions for reducing the house flies to a minimum. He lays great stress on the necessity of preventing children from defæcating in courts, passages, or stable middens. The danger lies in the overwhelming attraction which such fæcal matter has for house flies, which latter may afterwards come into direct contact with man or his foodstuffs. They may, as Vedeer puts it, "in a very few minutes ...... load themselves with dejections from a typhoid or dysenteric patient, not as yet sick enough to be in hospital or under observation, and carry the poison so taken up into the very midst of the food and water ready for use at the next meal. There is no long roundabout process involved." The use of sun-blinds in all shops containing food which attracts flies would largely reduce the number of flies in such places during hot weather. Small fruiterers' and confectioners' shops, as a rule, are not shaded by sun-blinds, and in their absence flies literally swarm on the articles exposed for sale. The final paper in the number is on Malaria and History, by W. H. S. Jones, M.A. It constitutes an interesting study of the history of malaria in ancient Greece and Rome. The author points out that disease has exercised considerable influence on the history of mankind and uses malaria as an illustration of this fact. The conclusion arrived at from the study of the history of both these races is that the decline was in both cases brought about to some extent, at any rate, by malaria. The paper is of great interest, and though some very large deductions are made from the premisses Mr. Jones argues quite fairly.

Proceedings of the Royal Society of Medicine, July, 1908.—The various sections in this number are chiefly occupied with reports of cases too numerous to be mentioned scope of the work which it is proposed to do. They will, in particular, require to be informed: (i.) what precautions the Local Education Authority will take to secure that only those children shall be treated in a School Clinic for whose treatment adequate provision cannot otherwise be made, whether by the parents or by voluntary associations or institutions, such as hospitals, or through the agency of the Poor Law; (ii.) what precise diseases and defects will be treated; (iii.) by whom and on what terms and conditions the treatment will be carried out and what will be its extent; (iv.) what is the estimated cost of the clinic in respect of buildings and equipment, maintenance and administration, and treatment, and how it is proposed to meet this cost, out of the rates or otherwise."

Looking Back.

FROM

THE LANCET, *SATURDAY*, Sept. 18th, 1830.

SEDATIVE QUALITIES OF THE WEB OF THE BLACK SPIDER.—The web of the black spider has received commendation from many respectable sources, as a sedative agent, capable of calming with peculiar ease and certainty, morbid excitability of the cerebral and nervous systems. On the credit of those qualities it has been employed in the various forms of temulence (exhaustion from intoxication), and not without a share of reputed success, sufficient to entitle it to consideration in that state of constitutional irritation. In the summer of 1827 we tried this article in many cases, and in full doses. To test its qualities, it was given, where the state of the patient admitted, uncombined with opiates. When thus used, its effects were generally partial or doubtful, and its powers inadequate to the production of tranquillity or sleep. In one case only have I found this substance to exert great or decided sedative attributes. This was the case of an intelligent young man, (in private practice,) who, after consuming, by his own report, three quarts of brandy, in thirty-six hours, fell into a state of temulent excitation so excessive, that he was incapable of keeping a recumbent, or even a sitting posture, for more than a moment, but paced his chamber with a ceaseless step for two days and nights. He was not delirious, on the contrary his conversation was rational, though hurried and vehement. But he was so far under the influence of spectral hallucination, that if he closed his eyes for a moment, day or night, he was instantly visited by a host of phantoms of frightful aspect; hence chiefly his aversion to lie down, or make any voluntary effort to sleep. This patient took opium, opium with camphor, and black drop at short intervals, and in full doses, until the quantum of opiate approached the utmost limit of probable safe administration, without even partial relief of constitutional irritation, or any apparent proneness to sleep. The temulent excitement kept unabated for twenty-four hours, the second night passed in constant vigilance, locomotion, and mental excitement; and it seemed probable that excitation so intense, protracted, and unremitting, must soon lapse into delirium or convulsions. At this time, the morning of the third day, (the second of my attendance,) he began the use of the fresh web in pills of five grains every hour. Its effect was prompt and unequivocal. He calmed, even sensibly to himself, with every dose, and watched with desire for the time of repeating the pills. The first effect of the web was to abate his restless movements about the room, he became disposed to sit down, and kept his chair, with short intervals of walking, for some hours. In the evening he consented to go to bed, got up once or twice, but returned to bed without difficulty, took an opiate at night, the first for eighteen hours, and slept continuously for eight hours. The cure was completed without difficulty, by repeating the web less frequently next day, with quiet, suitable nourishment, and another opiate at night. The patient spoke emphatically, both the first and second days, of the soothing influence produced by the pills.[1] He was not at the time informed of their composition.—*Dr. Wright, Amer. Journ.*

Public Health.

REPORTS OF MEDICAL OFFICERS OF HEALTH.

County Borough of Swansea.—Mr. Ebenezer Davies, the medical officer of health of Swansea, must be almost if not quite the father of the public health service, and in his current annual report he furnishes a "retrospect" of sanitary work in Swansea which carries us back far into the last century, to what is in effect, from the standpoint of time, the dawn of sanitation in this country. According to a report made in 1849 to the then General Board of Health by Mr. G. T. Clark, the superintending inspector, the deaths from consumption in the Swansea district, which included the Gower Peninsula, amounted to 1 in 4·8 of the total deaths; from "typhus," which probably included enteric fever and continued fever, 1 in 11; from "epidemics, including typhus," 1 in 3·5. The report referred to stated that "nothing deserving the name of a system of drainage can be said to exist," and the bulk of the population were dependent upon pumps and open watercourses for their water-supply. But at that time there was this redeeming feature that "single-family occupancy of houses was the rule," and Mr. Davies wishes that the same observation could be made now. Gradually a sort of public health conscience evolved and the desirability of carrying out the provision of the Public Health Act, 1848, was recognised. In September, 1853, Mr. M. H. Michael, an active member of the council, was appointed medical officer of health for 12 months at a salary of £150. Mr. Michael did some hard hitting and later the cholera arrived to emphasise his arguments. But the expense of carrying out Mr. Michael's recommendations was very great, violent opposition was encountered, and before the end of the year it was resolved that the appointment should not be renewed. Attempts to make another appointment were made but unsuccessfully, and it was not until 1865, when the historical outbreak of yellow fever occurred at Swansea, that, after a report by Dr. (afterwards Sir George) Buchanan, Mr. Davies was appointed medical officer of health in October, 1865, at £100 per annum. This appointment was therefore made before the Sanitary Act of 1866 rendered certain public health measures compulsory on sanitary authorities. It is of interest, having regard to the remarkable discoveries which have since been made, to recall the Swansea outbreak of yellow fever, since it is, we believe, the only occasion in which this disease has actually spread in England. The *Hecla*, the barque which was instrumental in introducing the disease, arrived off Swansea on Sept. 8th, 1865, there having been cases of illness on board the precise nature of which was not disclosed. Between Sept. 15th and Oct. 13th there were 22 cases, which were in all probability yellow fever, and seven others in which a strong suspicion of yellow fever attached to the illness. Of the 22 cases no fewer than 15 died. Of the 22 cases, 21 occurred in persons living or working in proximity to the infected ship or of that portion of the cargo which had been discharged, and there was no sufficient evidence to attribute the cases to personal infection. As Mr. Davies observes "persons lay sick of yellow fever in various parts of the town and no extension occurred from any of their centres, at least 12 in number." In the light of our present knowledge it would appear, therefore, that both the ship and the cargo retained living and infected stegomyia fasciata and that these insects did not wander far from ship or cargo, a view which receives support from recent researches as to the habits of stegomyia fasciata. In concluding his interesting retrospect in his fortieth annual report Mr. Davies compares the figures for the ten years 1866–75 with the ten years 1898–1907. In this interval the general death-rate was reduced from 23·6 to 17·7, the zymotic death-rate from 4·49 to 2·06, the "fever" death-rate from 0·75 to 0·09, and the phthisis death-rate from 2·18 to 1·45 per 1000 in each instance.

City of Newcastle.—Dr. Henry E. Armstrong's report contains a reference to nine cows which were found clinically affected with tuberculosis, four of them suffering from tuberculosis of the udder. Whilst these cows were in the cowsheds they were being milked twice daily and they were consequently "pouring tubercle bacilli into the milk pail." It would be interesting if Dr. Armstrong could watch the helpful. No doubt this little work will prove useful to those who are unable to consult the larger text-books upon the subject. It is a pity that so many errors in the spelling of proper names should have been left uncorrected.

[1] An article on Spider Pills was published in THE LANCET of June 25th, 1904, p. 1815.

First-Aid to Medical Treatment of Tamils and Singhalese, for the Use of Tea and Rubber Planters and Estate Dispensers. By R. J. DRUMMOND, M.D. Edin. Lindula: Walker and Greig. 1908. Pp. 58.—*The author of this book* has undertaken what is always a difficult task, that of supplying a medical guide for the use of non-medical persons in places where professional aid is unattainable. He disclaims any desire to let his book "compete with, or be a substitute for, the medical service that the Government have inaugurated in Ceylon," and rests the sanction for it in irrefutable words: "Every experienced tea-planter knows that a neglected 'cold' often leads to pneumonia and death; that a neglected diarrhœa often ends in dysentery and death; and that a neglected sore often ends in blood-poisoning and death." Dr. Drummond has not always quite hit the happy mean between teaching too much and teaching too little. In the opening section on Malaria, for instance, he describes a course of treatment extending over six weeks, including prescriptions containing arsenic, iron, and strychnine. Surely such after-treatment appertains rather to the medical officer than to the lay minister of first-aid. Nor would the latter profit much by reading of bronchitis: "If a stethoscope be applied to the chest the noise in the lung will be like a bellows blowing or the crackling sound of a distant fire on grass patnas." However, the book contains a trustworthy and useful symptomatology and guide to treatment of the commoner diseases written in plain language, although it must be confessed in terribly slipshod grammar. The treatment of cholera and dysentery is very thoroughly described in what are perhaps the best sections in the book. There is a very brief account of surgical first-aid; and an interesting section, headed "Medico-Legal," on native poisoning practices and caste punishments, which includes a terrible account of infanticide, "a very common crime in Ceylon," affords a startling criticism on the protection afforded by the British Raj to the caste-ridden native. Dr. Drummond's little book should command a wide circulation in the Ceylon tea-gardens, and in intelligent hands will prove of considerable utility. The preface shows it to have been written in response to a request for such a work from those to whom it is addressed.

JOURNALS AND MAGAZINES.

Annals of Tropical Medicine and Parasitology, University of Liverpool. Vol. I., No. 4. Illustrated. London: Williams and Norgate. Pp. 71. Price 7*s* 6*d.* net.—The investigation and suggestions for preventing the so-called "Canary fever," by Mr. C. E. Walker, form the first paper in this number. We have already printed an abstract of it in THE LANCET of June 13th, p 1707. An interesting study of a somewhat rare disease caused by a parasitic worm, "porocephalus moniliformis," by Dr. A. Broden and Dr. J. Rodhain from the Leopoldville Laboratory in the Congo Free State, is contained in the second paper. The patient whose case is described showed extreme tenderness in the left hypochondriac region and parts of the epigastrium. The liver was not enlarged, but there was some slight engorgement of the base of the left lung. He was extremely constipated and vomited a certain amount of blood. After about four weeks' illness he died quite suddenly. The intestine and peritoneal cavity were full of some long bacilli which were anaerobic but which have not been identified. Only one larva of the worm was found, but many hæmorrhagic patches and pockets were found in the small intestine. A detailed description of the worm is given. Mr. Robert Newstead contributes a paper on the Habits, Life-Cycle, and Breeding Places of the Common House Fly. The results of the investigations described should prove very valuable, both from an economic and a scientific standpoint. The chief breeding places of the house fly apparently are—middensteads containing horse manure only; middensteads containing spent hops; and ashpits containing fermented material. Mr. Newstead found that in stable-yards where poultry were kept and allowed to wander about freely flies were kept under to a very great extent, and that while both open and closed ashpits were infested with the larvæ the flies gave preference to the closed receptacles. The non-breeding places were—middens containing excessively moist and non-fermented cow-dung; patent ash-bins; refuse in ashpits saturated with water; and human excreta lying in courts and passages. After dealing with the life-cycle of the common house fly the author summarises his observations as follows: That covered ashpits and middens were as badly infested as those which were open. That house flies breed in all temporary collections of fermenting matter. That house flies breed in relatively small numbers in ashpits where no fermentation takes place. That they do not breed in ashpits which are emptied at short intervals or in the patent bins. That the use of disinfectants in ashpits does not prevent the flies breeding in such receptacles. That very dry or excessively wet ashes or moist cow-dung does not harbour them. That the life-cycle of the fly in all kinds of fermenting materials is reduced to the minimum period *of from 10 to 14 days, and that in the* absence of such artificial heat the cycle may occupy a period of from three to five weeks or more, according to the temperature of the outside air. That house flies do not depend entirely upon excessively warm weather for breeding purposes, though in hot seasons they would breed much more rapidly in non-fermenting materials and their numbers under such conditions would be greatly increased. He makes various suggestions for reducing the house flies to a minimum. He lays great stress on the necessity of preventing children from defæcating in courts, passages, or stable middens. The danger lies in the overwhelming attraction which such fæcal matter has for house flies, which latter may afterwards come into direct contact with man or his foodstuffs. They may, as Vedeer puts it, "in a very few minutes ...... load themselves with dejections from a typhoid or dysenteric patient, not as yet sick enough to be in hospital or under observation, and carry the poison so taken up into the very midst of the food and water ready for use at the next meal. There is no long roundabout process involved." The use of sun-blinds in all shops containing food which attracts flies would largely reduce the number of flies in such places during hot weather. Small fruiterers' and confectioners' shops, as a rule, are not shaded by sun-blinds, and in their absence flies literally swarm on the articles exposed for sale. The final paper in the number is on Malaria and History, by W. H. S. Jones, M.A. It constitutes an interesting study of the history of malaria in ancient Greece and Rome. The author points out that disease has exercised considerable influence on the history of mankind and uses malaria as an illustration of this fact. The conclusion arrived at from the study of the history of both these races is that the decline was in both cases brought about to some extent, at any rate, by malaria. The paper is of great interest, and though some very large deductions are made from the premisses Mr. Jones argues quite fairly.

Proceedings of the Royal Society of Medicine, July, 1908.—The various sections in this number are chiefly occupied with reports of cases too numerous to be mentioned been equal to 15·8, 15·6, and 14·6 in the three preceding weeks, further declined to 14·2 in the week under notice. During the first 11 weeks of the current quarter the annual death-rate in these towns averaged 13·3 per 1000, and in London the mean rate in the same period did not exceed 12·3. The lowest annual death-rates in these 76 towns during the week under notice were 6·4 in Ipswich, 6·7 in Barrow-in-Furness, and 7·3 in Hornsey and in Grimsby; the rates in the other towns ranged upwards, however, to 20·8 in Liverpool and in Tynemouth, 20·9 in Birkenhead, 22·4 in Stockport, and 27·3 in Burnley. In London the death-rate during the week did not exceed 13·3. The 4433 deaths from all causes in the 76 towns showed a further decline of 110 from the numbers returned in the three preceding weeks, and included 840 which were referred to the principal epidemic diseases, against 1343 and 1067 in the two preceding weeks; of these 840 deaths, 668 resulted from diarrhœa, 52 from whooping-cough, 39 from diphtheria, 34 from "fever" (principally enteric), 25 from measles, and 21 from scarlet fever, but not one from small-pox. The deaths referred to these epidemic diseases during the week under notice were equal to an annual rate of 2·7 per 1000, against 4·3 and 3·4 in the two preceding weeks; in London the death-rate from these epidemic diseases last week did not exceed 2·4. No death from any of these epidemic diseases was registered last week in West Hartlepool, Newport, Wallasey, or Hastings, whereas the annual death-rates therefrom ranged upwards in the other large towns to 6·6 in Coventry, 7·0 in Oldham, 8·3 in Hull, and 11·4 in Burnley. The deaths attributed to diarrhœa in the 76 towns, which had been 1134, 1123, and 889 in the three preceding weeks, further declined to 668 in the week under notice; they caused, however, annual death-rates ranging upwards to 5·3 in Walsall and in Coventry, 7·7 in Hull, and 9·9 in Burnley. The 52 fatal cases of whooping-cough exceeded those in the previous week by two; they were proportionally most numerous in Coventry, Merthyr Tydfil, and Burnley. The 39 deaths from diphtheria also showed an increase, and caused death-rates equal to 1·5 in Bootle and 2·0 in Stockton-on-Tees. The 34 deaths referred to "fever" showed a further increase upon recent weekly numbers, and exceeded the number returned in any previous week of the year; the highest death-rates from this disease last week were 1·4 in Bolton and 1·6 in Rotherham. The 25 fatal cases of measles and the 21 of scarlet fever both showed a distinct decline, those of measles being considerably fewer than in any previous week of this year; measles caused, however, death-rates equal to 1·5 in Oldham and 1·8 in Rochdale, and scarlet fever caused six deaths in Liverpool and Birkenhead and three in Salford. The number of scarlet fever patients under treatment in the Metropolitan Asylums and the London Fever Hospitals, which had been 2825 and 2855 in the two preceding weeks, had further risen to 3005 on Sept. 12th; the number of new cases of this disease admitted to these hospitals during the week under notice were 472, against 377 and 395 in the two previous weeks. The deaths in London referred to pneumonia and other diseases of the respiratory organs, which had been 132 and 102 in the two preceding weeks, rose again last week to 124, but were three below the corrected average number in the corresponding week of the five years 1903–07. The causes of 49, or 1·1 per cent., of the deaths registered in the 76 towns last week were not certified either by a registered medical practitioner or by a coroner. All the causes of death were again duly certified in Bristol, West Ham, Bradford, Leicester, Newcastle-on-Tyne, Nottingham, and in 47 other smaller towns during the week under notice; nine uncertified causes of death were, however, registered during the week in Liverpool, six in Birmingham, four in Hull, and three both in Preston and in South Shields.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in eight of the principal Scotch towns, which had been equal to 15·4 and 14·8 per 1000 in the two preceding weeks, further declined to 13·7 in the week ending Sept. 12th. During the first 11 weeks of the current quarter the annual death-rate in these eight towns averaged 13·8 per 1000 and exceeded by 0·5 the mean rate during the same period in the 76 English towns. Among the eight Scotch towns the death-rate during the week under notice ranged from 8·8 and 10·4 in Aberdeen and Perth to 14·7 in Glasgow and in Edinburgh, and 15·3 in Greenock. The 484 deaths in the eight towns showed a further decline of 39 from the numbers in the two previous weeks, and included 87 which were referred to the principal epidemic diseases, against 107, 96, and 95 in the three preceding weeks; of these 87 deaths, 52 resulted from diarrhœa, 18 from whooping-cough, five from "fever," five from diphtheria, four from measles, and three from scarlet fever, but not one from small-pox. These 87 deaths were equal to an annual rate of 2·5 per 1000, which was 0·2 below the mean rate from the same diseases in the 76 large English towns. The deaths attributed to diarrhœa in the eight Scotch towns, which had been 60 and 64 in the two preceding weeks, declined to 52 in the week under notice, and included 26 in Glasgow, six in Edinburgh and in Dundee, five in Greenock, and four both in Leith and in Aberdeen. The 18 fatal cases of whooping-cough were within one of the number in the previous week; 11 occurred in Glasgow and four in Dundee. The five deaths referred to "fever" exceeded the number in the previous week by one, all being certified as cases of cerebro-spinal meningitis; four were returned in Glasgow and one in Aberdeen. Three of the five fatal cases of diphtheria and all the four deaths from measles occurred in Glasgow. The deaths referred to diseases of the respiratory organs in the eight towns, which had been 75 and 57 in the two preceding weeks, further declined to 44 in the week under notice, and were 17 below the number returned in these towns in the corresponding week of last year. The causes of 16, or 3·3 per cent., of the deaths registered in the eight towns during the week were not certified; in the 76 English towns during the same week the proportion of uncertified causes of death did not exceed 1·1 per cent.

HEALTH OF DUBLIN.

The annual rate of mortality in Dublin, which had been equal to 24·1, 22·5, and 21·7 per 1000 in the three preceding weeks, further declined to 20·6 in the week ending Sept. 12th. During the first 11 weeks of the current quarter the death-rate in Dublin averaged 19·9 per 1000; the mean rate during the same period did not exceed 12·3 in London and 13·1 in Edinburgh. The 156 deaths of Dublin residents during the week under notice showed a further decline of eight from the high numbers returned in recent weeks, and included 28 which were referred to the principal epidemic diseases, against 44, 35, and 37 in the three preceding weeks. These 28 deaths were equal to an annual rate of 3·7 per 1000; the rate during the week from the same diseases did not exceed 2·4 in London and 1·0 in Edinburgh. Of the 28 deaths from these epidemic diseases in Dublin during the week under notice, 20 resulted from diarrhœa, six from measles, and one each from whooping-cough and "fever," but not one from scarlet fever, diphtheria, or small-pox. The deaths attributed to diarrhœa, which had been 39, 26, and 28 in the three preceding weeks, further declined to 20 in the week under notice. The six fatal cases of measles corresponded with the number in the previous week. The 156 deaths from all causes during the week included 47 of infants under one year of age and 27 of persons aged upwards of 60 years; both these numbers showed a considerable decline from the numbers returned in recent weeks. Four inquest cases and three deaths from violence were registered; and 58, or 37·4 per cent., of the deaths occurred in public institutions. The causes of seven, or 4·5 per cent., of the deaths registered during the week were not certified; in London the causes of all but one of the 1221 registered deaths were duly certified, while in Edinburgh the proportion of uncertified causes of death was equal to 6·0 per cent.

VITAL STATISTICS OF LONDON DURING AUGUST, 1908.

IN the accompanying table will be found summarised complete statistics relating to sickness and mortality in the City of London and in each of the metropolitan boroughs. With regard to the notified cases of infectious diseases, it appears that the number of persons reported to be suffering from one or other of the nine diseases specified in the table was

THE LANCET.

LONDON: SATURDAY, SEPTEMBER 19, 1908.

The Sixty-Second Report of the Commissioners in Lunacy.

THE statistics contained in this report are not materially different from similar statistics of the last few years and there is a continued increase in the number of insane persons known to be under care. The number of such persons on Jan. 1st, 1907, was 123,988 and on Jan. 1st, 1908, was 126,084, being an increase of 2096. As, however, the annual average increase for the ten years ending with 1907 was 2411 the increase for 1907 was less by 315 than the annual average of the decennium. It was found that the ratio of notified insane persons to the estimated population was on Jan 1st, 1908, 1 to 280, or 35·67 per 10,000. This is an increase on the ratio of the year before of 0·53 per cent. and an actual numerical increase of nearly 1·7 per cent. At the beginning of 1898 the ratio of insane persons to the estimated population was 32·35, so that since then it has increased by as much as 10·2 per cent., the proportion of insane persons having risen from 1 in 309 to 1 in 280. The increase in the whole population has been 12·2 per cent., while in the number of the insane it has been 23·7 per cent. Examining the ratio for a larger number of years we find that while the estimated population increased by 57·2 per cent. between the years 1869 and 1907 the total number of the known insane increased by 137·1 per cent. The ratio of the insane to the population was at the beginning of 1869 23·93 per 10,000 and on Jan. 1st of this present year 35·67 per 10,000, being an increase of 49 per cent. The ratios for first admissions were 4 92 per 10,000 in 1898, 5·76 in 1902, 5·16 in 1906, and 5 18 in 1907. The number of patients at the beginning of 1907, not counting those in idiot establishments, in institutions, and in single private care, was 98,521, being an increase of 32 per cent. on the number under similar care at the beginning of 1897. During these ten years the numbers in county and borough asylums had increased by 36·6 per cent., in registered hospitals by 3·6 per cent., in the State asylums by 26·4 per cent., and in single care by 17·3 per cent.

It appears that nearly three-fourths of the number of patients annually certified are suffering from their first attack, while the remainder represent recurrent cases. The report points out that it is highly probable that, at any rate among certain classes, the too speedy return to old avocations and the environment under which the patient originally broke down contributes to the recurrence of the malady. It may be that at some future date it will be more widely recognised to be desirable that the patient should be subjected to a more careful supervision on his discharge from the asylum. To this end it may be found necessary to establish convalescent homes where the recovery of patients may be still further insured. The After-Care Association, unfortunately only in a very small way, undertakes at the present time to do what it can for discharged patients and deserves far more support from the public than it receives. It is quite possible that a considerable extension of this work might contribute in no small degree to a decrease in the amount of insanity in this country.

We are happy to note that the Commissioners are very decidedly of opinion that the asylums should be utilised to further the scientific study of insanity and higher medical education. Too often the asylum is regarded rather as a place of detention where persons who are a nuisance to the community are confined, instead of a place of refuge for the sufferer where he may obtain appropriate treatment for his disease. We cannot, however, but feel that there are indications that the public are beginning to regard insanity as a disease which is to be studied and treated in precisely the same way as are those diseases in which disordered function is more obviously the result of organic alteration of the tissues. A substantial part of this excellent change in public opinion must be attributed to the earnest scientific labours of those working in this branch of our science and art, their labours involving investigations in the phenomena of mind and in the structure and function of its delicate instrument and constant servant, the brain. But perhaps a yet larger factor in the production of this change has been the work of the Commission in Lunacy. From a disorderly and sometimes disgraceful chaos there has been evolved under its guidance a systematisation of philanthropic effort for the amelioration of the condition of the insane. The work of the Commission is now of such extent that it cannot be efficiently performed by the present number of the Commissioners. That the best that can be done is being done there can be no doubt from a perusal of the report now before us. But times have changed and the large increase of the insane population demands a larger Commission and one in which less prominence shall be given to what we may call its police functions and more to the more strictly medical aspects of the work. We trust that the adoption of some of the recommendations of the Royal Commission on the Feeble-Minded[1] may eventuate in such an improvement.

◆

Huntington's Chorea or Chronic Progressive Chorea.

THIRTY-SIX years ago Dr. GEORGE HUNTINGTON, then a recently qualified practitioner of but 22 years of age, at the end of a paper on the subject of chorea in childhood, gave a description in a few strikingly graphic sentences of that peculiar form of chorea which has since that time been generally called after him, a description so complete and so distinctive that from a clinical standpoint little or nothing has since been added. It is always interesting, stimulating, and instructive to study the history of any scientific advance and to trace the evolution of knowledge in regard to it. We have received an interesting pamphlet[2] which, though of modest dimensions and of unpretentious character, is a very equal to an annual rate of 6·3 per 1000 of the population, estimated at 4,795,757 persons in the middle of the year; in the three preceding months the rates were 6·2, 5·6, and 6·5 per 1000 respectively. The lowest rates last month were recorded in Chelsea, the City of Westminster, Hampstead, Stoke Newington, and Holborn; and the highest rates in Shoreditch, Bethnal Green, Stepney, Poplar, Battersea, and Deptford. Scarlet fever was less prevalent during August than it had been in the preceding month; the greatest proportional prevalence of this disease was recorded in Shoreditch; Bethnal Green, Stepney, Poplar, Battersea, and Deptford. The number of scarlet fever patients under treatment in the Metropolitan Asylums Hospitals was 2807 at the end of August, against 2707, 2514, and 2693 at the end of the three preceding months; the weekly admissions averaged 365, against 307 and 372 in the two preceding months. The prevalence of diphtheria showed a slight increase over that recorded in the two preceding months; this disease was proportionally most prevalent in Hammersmith, Fulham, Hackney, Stepney, Bermondsey, Greenwich, Lewisham, and Woolwich. The Metropolitan Asylums Hospitals contained 843 diphtheria patients at the end of last month, against 804, 768, and 738 at the end of the three preceding months; the weekly admissions averaged 110, against 105, 95, and 100 in the three preceding months. Enteric fever was slightly more prevalent than in other recent months; among the various metropolitan boroughs this disease showed the greatest proportional prevalence in Chelsea, Hampstead, St. Pancras, Finsbury, Shoreditch, Stepney, and Woolwich. The number of enteric fever patients under treatment in the Metropolitan Asylums Hospitals, which had been 45, 48, and 54 at the end of the three preceding months, had further risen to 69 at the end of last month; the weekly admissions averaged 12, against seven, eight, and nine in the three preceding months.. Erysipelas was proportionally most prevalent in St. Pancras, Hackney, Bethnal Green, Stepney, Southwark, and Deptford. The 17 cases of puerperal fever notified during the month included two each in Kensington, Hammersmith, Fulham, Southwark, and Wandsworth. One case of cerebro-spinal meningitis was recorded in Fulham and one in Bermondsey.

---

[1] See p 890 of our present issue.

[2] Neurographs, vol. I., No. 2. Huntington Number. Brooklyn, New York - Albert T. Huntington. 1908.

The mortality statistics in the table relate to the deaths of persons actually belonging to the various boroughs, the deaths occurring in institutions having been distributed among the boroughs in which the deceased persons had previously resided. During the four weeks ending August 29th the deaths of 4755 persons belonging to London were registered, equal to an annual rate of 12·9 per 1000; in the three preceding months the rates had been 12·2, 10·4, and 10·3 per 1000. The rates of mortality last month in the several boroughs ranged from 5·5 in Hampstead, 8·7 in the City of Westminster, 8·9 in Stoke Newington, 10·2 in St. Marylebone, 10·3 in Woolwich, and 10·4 in Lewisham, to 16·0 in Stepney, 16·5 in Southwark, 17·3 in Poplar, 18·0 in Shoreditch, 18·7 in Bethnal Green, 20·4 in Finsbury, and 21·7 in Bermondsey. The 4755 deaths from all causes included 1041 which were referred to the principal infectious diseases; of these, 97 resulted from measles, 37 from scarlet fever, 43 from diphtheria, 51 from whooping-cough, 11 from enteric fever, and 802 from diarrhœa, but not any from small-pox, from typhus fever, or from ill-defined pyrexia. The lowest death-rates from these infectious diseases were recorded in the Cities of London and Westminster, and the boroughs of St. Marylebone, Hampstead, Stoke Newington, and Woolwich; and the highest rates in Finsbury, Shoreditch, Bethnal Green, Stepney, Poplar, Southwark, and Bermondsey. The 97 deaths from measles were slightly below the corrected average number in the corresponding period of the five preceding years; this disease was proportionally most fatal in Finsbury, Bethnal Green, Stepney, Poplar, Southwark, Bermondsey, and Deptford. The 37 fatal cases of scarlet fever were equal to the corrected average number; the greatest proportional mortality from this disease was recorded in Hammersmith, Chelsea, Shoreditch, Bethnal Green, Stepney, Bermondsey, and Battersea. The deaths from diphtheria numbered 43, against an average of 47 in the corresponding weeks of the five preceding years; this disease showed the greatest proportional mortality in Fulham, Stepney, Poplar, Greenwich, and Lewisham. The 51 fatal cases of whooping-cough were 27 fewer than the corrected average number; the highest death-rates from this disease were recorded in Hammersmith, St. Pancras, Islington, Hackney, Poplar, Southwark, Wandsworth, and Greenwich. The 11 deaths referred to enteric fever were equal to only one-half of the corrected average; of these 11 deaths, three belonged to Bethnal Green and one to each of eight other boroughs. The 802 fatal cases of diarrhœa showed a decline of 470 from the corrected average number; this disease was proportionally most fatal in Finsbury, Shoreditch, Bethnal Green, Stepney, Poplar, Southwark, and Bermondsey. In conclusion, it may be stated that the aggregate mortality from these principal infectious diseases in London last month was 33 per cent. below the average.

Infant mortality, measured by the proportion of deaths among children under one year of age to registered births, was equal to 167 per 1000. The lowest rates of infant mortality were recorded in St. Marylebone, Hampstead, Stoke Newington, Holborn, Lewisham, and Woolwich; and the highest rates in the City of London, Shoreditch, Bethnal Green, Poplar, Southwark, Bermondsey, and Greenwich.

THE SERVICES.

ROYAL NAVY MEDICAL SERVICE.

IN accordance with the provisions of Her late Majesty's Order in Council of April 1st, 1881, Surgeon David Hadden Vickery has been allowed to withdraw from His Majesty's Naval Service with a gratuity (dated Sept. 12th, 1908).

The following appointment is notified: Staff-Surgeon C. J. E. Cock to the *President*, additional, for three months' course of study at West London Hospital.

ROYAL ARMY MEDICAL CORPS.

Lieutenant-Colonel R. Kirkpatrick, C.M.G., has joined at Devonport for duty as medical officer in charge of the Military Hospital, in the place of Colonel H. G. Hathaway, who has been appointed administrative medical officer at Portsmouth. Lieutenant Harold Græme Gibson has been appointed for duty with the South Western Coast Defences. Lieutenant-Colonel W. M. James has been appointed to the medical charge at Guildford.

Lieutenant George B. F. Churchill to be Captain (dated July 31st, 1908).

Lieutenant-Colonel Henry L. Battersby is placed on retired pay (dated Sept. 7th, 1908).

ARMY MEDICAL RESERVE OF OFFICERS.

Surgeon-Captain George G. Oakley to be Surgeon-Major (dated Sept. 2nd, 1908).

ROYAL ARMY MEDICAL CORPS (MILITIA).

Captain William V. Sinclair is granted the honorary rank of Major (dated August 14th, 1908).

TERRITORIAL FORCE.

Royal Army Medical Corps.

2nd East Anglian Field Ambulance: Supernumerary Surgeon-Major John Herbert Stacy, from the 1st Volunteer Battalion, The Norfolk Regiment, to be Lieutenant-Colonel (dated 1st April, 1908). Surgeon-Major Samuel John James Kirby, from the 2nd Volunteer Battalion, The Norfolk Regiment, to be Major, with precedence as in the Volunteer Force (dated April 1st, 1908). Supernumerary Surgeon-Captain George Blake Masson, from the 3rd Volunteer Battalion, The Norfolk Regiment, to be Captain, with precedence as in the Volunteer Force (dated April 1st, 1908); Supernumerary Surgeon-Captain James Morrison Gardiner Bremner from the 1st Volunteer Battalion, The Norfolk Regiment, to be Captain, with precedence as in the Volunteer Force (dated April 1st 1908).

1st Home Counties Field Ambulance: Major Charles Pye Oliver from the Eastern Command, Maidstone Companies, Royal Army Medical Corps (Volunteers) to be Lieutenant-Colonel (dated April 1st, 1908).

The undermentioned officers from the Eastern Command, Maidstone Companies, Royal Army Medical Corps (Volunteers), are appointed to the Ambulance, with rank and precedence as in the Volunteer Force (dated April 1st, 1908): Captain John Monkhouse Rogers-Tilstone, Lieutenant John Aldington Gibb, Lieutenant Joseph Ward, and Lieutenant Arthur Thomas Falwasser. Supernumerary Surgeon-Captain William James Woodman,

THE LANCET.

LONDON: SATURDAY, SEPTEMBER 19, 1908.

The Sixty-Second Report of the Commissioners in Lunacy.

THE statistics contained in this report are not materially different from similar statistics of the last few years and there is a continued increase in the number of insane persons known to be under care. The number of such persons on Jan. 1st, 1907, was 123,988 and on Jan. 1st, 1908, was 126,084, being an increase of 2096. As, however, the annual average increase for the ten years ending with 1907 was 2411 the increase for 1907 was less by 315 than the annual average of the decennium. It was found that the ratio of notified insane persons to the estimated population was on Jan. 1st, 1908, 1 to 280, or 35·67 per 10,000. This is an increase on the ratio of the year before of 0·53 per cent. and an actual numerical increase of nearly 1·7 per cent. At the beginning of 1898 the ratio of insane persons to the estimated population was 32·35, so that since then it has increased by as much as 10·2 per cent., the proportion of insane persons having risen from 1 in 309 to 1 in 280. The increase in the whole population has been 12·2 per cent., while in the number of the insane it has been 23·7 per cent. Examining the ratio for a larger number of years we find that while the estimated population increased by 57·2 per cent. between the years 1869 and 1907 the total number of the known insane increased by 137·1 per cent. The ratio of the insane to the population was at the beginning of 1869 23·93 per 10,000 and on Jan. 1st of this present year 35·67 per 10,000, being an increase of 49 per cent. The ratios for first admissions were 4·92 per 10,000 in 1898, 5·76 in 1902, 5·16 in 1906, and 5·18 in 1907. The number of patients at the beginning of 1907, not counting those in idiot establishments, in institutions, and in single private care, was 98,521, being an increase of 32 per cent. on the number under similar care at the beginning of 1897. During these ten years the numbers in county and borough asylums had increased by 36 6 per cent., in registered hospitals by 3·6 per cent., in the State asylums by 26·4 per cent., and in single care by 17·3 per cent.

It appears that nearly three-fourths of the number of patients annually certified are suffering from their first attack, while the remainder represent recurrent cases. The report points out that it is highly probable that, at any rate among certain classes, the too speedy return to old avocations and the environment under which the patient originally broke down contributes to the recurrence of the malady. It may be that at some future date it will be more widely recognised to be desirable that the patient should be subjected to a more careful supervision on his discharge from the asylum. To this end it may be found necessary to establish convalescent homes where the recovery of patients may be still further insured. The After-Care Association, unfortunately only in a very small way, undertakes at the present time to do what it can for discharged patients and deserves far more support from the public than it receives. It is quite possible that a considerable extension of this work might contribute in no small degree to a decrease in the amount of insanity in this country.

We are happy to note that the Commissioners are very decidedly of opinion that the asylums should be utilised to further the scientific study of insanity and higher medical education. Too often the asylum is regarded rather as a place of detention where persons who are a nuisance to the community are confined, instead of a place of refuge for the sufferer where he may obtain appropriate treatment for his disease. We cannot, however, but feel that there are indications that the public are beginning to regard insanity as a disease which is to be studied and treated in precisely the same way as are those diseases in which disordered function is more obviously the result of organic alteration of the tissues. A substantial part of this excellent change in public opinion must be attributed to the earnest scientific labours of those working in this branch of our science and art, their labours involving investigations in the phenomena of mind and in the structure and function of its delicate instrument and constant servant, the brain. But perhaps a yet larger factor in the production of this change has been the work of the Commission in Lunacy. From a disorderly and sometimes disgraceful chaos there has been evolved under its guidance a systematisation of philanthropic effort for the amelioration of the condition of the insane. The work of the Commission is now of such extent that it cannot be efficiently performed by the present number of the Commissioners. That the best that can be done is being done there can be no doubt from a perusal of the report now before us. But times have changed and the large increase of the insane population demands a larger Commission and one in which less prominence shall be given to what we may call its police functions and more to the more strictly medical aspects of the work. We trust that the adoption of some of the recommendations of the Royal Commission on the Feeble-Minded[1] may eventuate in such an improvement.

◆

Huntington's Chorea or Chronic Progressive Chorea.

THIRTY-SIX years ago DR. GEORGE HUNTINGTON, then a recently qualified practitioner of but 22 years of age, at the end of a paper on the subject of chorea in childhood, gave a description in a few strikingly graphic sentences of that peculiar form of chorea which has since that time been generally called after him, a description so complete and so distinctive that from a clinical standpoint little or nothing has since been added. It is always interesting, stimulating, and instructive to study the history of any scientific advance and to trace the evolution of knowledge in regard to it. We have received an interesting pamphlet[2] which, though of modest dimensions and of unpretentious character, is a very

---

[1] See p. 890 of our present issue.

[2] Neurographs, vol. I., No. 2. Huntington Number. Brooklyn, New York - Albert T. Huntington. 1908.

Surgeon-Lieutenant Andrew Edward Hodder, from the 1st Volunteer Battalion, The Manchester Regiment.

VOLUNTEER OFFICERS' DECORATION.

The Volunteer Officers' Decoration has been conferred upon the following:—

London District: (Infantry Volunteers): 2nd Bucks (Eton College) Volunteer Rifle Corps; Surgeon-Major Edward Stacy Norris.

Scottish Command: Infantry (Volunteers): The Queen's Rifle Volunteer Brigade, The Royal Scots (Lothian Regiment): Surgeon-Major John Hugh Alexander Laing. 1st Dumbartonshire Volunteer Rifle Corps: Surgeon-Lieutenant-Colonel John Robert Fleming Cullen (retired).

DEATHS IN THE SERVICES.

Fleet-Surgeon Richard Eustace, R.N., at Bournemouth, on Sept. 10th, aged 75 years. He entered the service in 1854, was appointed staff-surgeon in 1862, fleet-surgeon in 1874, and retired in 1879. He served as assistant surgeon in the Baltic in 1854, and in the flagship of Rear-Admiral Bruce, Commander-in-Chief, Pacific Station, at Petropaulovski in 1855, during the Russian war of 1854–55 (Baltic medal). He also served as staff-surgeon in the *Himalaya* on the Gold Coast during the Ashantee war (Ashantee medal), and received the thanks of the Admiralty for the care of the sick in the troopship and was specially promoted to (staff) fleet-surgeon. He was awarded the Sir Gilbert Blane gold medal for "Medical and Surgical Journal of 1873," containing, among other matters, an account of the intermittent and remittent fevers and malarious forms of dysentery, which decimated the greater part of the Royal Marines landed on the Gold Coast in the summer of 1873.

THE ARMY AND NAVY MALE NURSES' COOPERATION.

The report of the executive committee of this coöperation, which was received at the first annual general meeting held on July 31st at 47B, Welbeck-street, under the presidency of Sir Frederick Treves, Bart., G.C.V.O., C.B., has now been published in the form of a pamphlet. It can be obtained from the secretary at the offices of the society. The report points out that the system of male nursing in England at this moment is inefficient and imperfectly organised but that the association is doing much to improve it by keeping together a class of men who have already been trained for a valuable calling.

TERRITORIAL FORCE AND CIVIL PRACTITIONERS.

Civil practitioners are not to be engaged for the medical charge of units of the Territorial Force at the annual training in camp at payment exceeding contract rates without previous authority.

TESTING THE VISION IN SCHOOL CHILDREN.

To the Editor of THE LANCET.

SIR,—The letter in THE LANCET of Sept. 12th by Dr. J. S. C. Elkington on an Improved Method of Testing Distant Vision Acuity in Schools leads me to say that all inspectors of such a function as the eyesight should be fully conversant with the use of the retinoscopical mirror—preferably a large "flat" mirror. All tests carried out by the usual methods of expressing what is seen at a certain distance are fundamentally defective, for the very simple fact that the individual whose eyeball is axially of a perfect length is the very one who ought to be most carefully examined in that there is no material left to allow for extension of the tunics of the eyeball. In other words, the more correct in shape an eyeball is in a young subject the more liable is short sight to come on if at any time the natural elasticity of the tunics of the eyeball should be lost. By means of the shadow test any approach to exactness of axial length can be instantly gauged, and if a note of such be kept a future examination will at once reveal whether any stretching has taken place. Further, the general condition of the child if at all inclined to be weakly would under such circumstances lead one to warn parents and teachers to keep careful observation on the child's near work—in fact, lead them to anticipate myopic "habits" *before* their onset. Were such children tested by the reading chart at 6 metres no defect would be discovered until *myopia had set in*, whereas had the mirror test been employed a "*tendency* to myopia" could be discovered or suspected before mischief had occurred. This anticipatory attribute of retinoscopy is the chief, but not only, reason for its adoption. It is just as expeditious and far quicker in practice in discovering hypermetropia and astigmatism. Moreover, one need not be an expert refractionist to be able to carry out the test. All that one requires is the mirror and convex lenses of 1, 1·5, and 2. The child is seated at a full arm's length from the examiner and beneath any ordinary light in a darkened room or even under the shade of an umbrella. Now the observer notes the direction of the moving shadow which is made on the pupil of the child's eye by the beam of parallel rays thrown on it by the flat mirror. If the shadow move against the direction of the beam of light we know at once the eye under observation is myopic or nearly so and, at all events, requires attention of the specialist. If, however, the shadow "move with" the motion of the mirror all that is required is to find which lens of the three possessed by the observer reverses it. If + 1 reverses, the patient should be referred to a specialist, as the eye is probably so nearly correct that actual presence of, or any tendency to, myopia must be excluded before the child is allowed to continue its studies. If, however, + 1·5 or + 2 reverse, it is advisable to try the other eye to see if there be much difference between them. Should this be the case further examination is imperative. When these lens reverse the shadow in both eyes nothing further need be done unless symptoms, such as headaches, eye-strain, &c., are complained of. Should no reversal be obtained superimpose the + 1 and + 1·5 lens, or the + 2 with either of these, and if no reversal follows we can be sure that we have to deal with a case of hypermetropia which will require the use of atropine. Reversal obtained by lenses below or of 3 D. can be left untreated unless eye-strain symptoms are complained of. In a similar manner errors of astigmatism are rapidly discovered; in fact, in many cases one glance at the line of light which is so palpably evident in astigmatism gives the case away at once without any need of the confirmatory evidence of the plus lenses. All the above cases in the great majority of instances can easily pass the visual acuity reading test and in unlearned children afford the only reliable test possible. Regarding the time occupied in testing by the reading type *versus* the mirror test there is no question which is the more rapid, and for this reason alone it is worth cultivating. Finally, in that it exposes the real axial length of the eye at the time when the vision is best and *before the onset* of myopia its adoption should be compulsory. The compulsory examination of children in public schools is one of the greatest blessings for the coming generation which have evolved by the aid of law for many years, but its great failing is that we cannot apply it to our private schools where *it is so much more needed*, at least as regards vision; hence it is the duty of all medical men to instruct their better-class patients to see that their children are sent to schools where they will at least have the same treatment as is given to that of our working classes.

I am, Sir, yours faithfully,
A. ALISON BRADBURNE, F.R.C.S. Edin.
Ophthalmic Surgeon, Southport School Board, &c.

Sept. 14th, 1903.

EXHIBITION AT THE CLINICAL MUSEUM.

To the Editor of THE LANCET.

SIR,—May I be allowed to inform your readers that we are preparing in the Clinical Museum a third classified exhibition of drawings, &c., and shall much value any assistance which they may incline to give us. Great care will be taken of all exhibits which may be sent on loan. The exhibition will deal with syphilis and all that concerns it. It will be arranged under the heads of primary, secondary, and tertiary phenomena and will give especial attention, amongst others, to the following subjects: erratic chancres, the classification and diagnosing of non-indurated sores (the ulcus molle), malignant syphilis, framboesial syphilis, serpiginous or lupoid syphilis, syphilis of viscera, ophthalmoscopic conditions, the teeth, histology, and parasitism. The microscopic department itself has unfortunately been lost, or at any rate cannot be traced. The third account of the disease was given in an article by Dr. IRVING W. LYON published in the *American Medical Times* of Dec. 19th, 1863, with the title, "Chronic Hereditary Chorea." He did not indicate the locality in which his cases occurred but seems to have recognised all the general features of the disease. It is thus obvious that Dr. HUNTINGTON'S observations were not the earliest record of this disease, but his was the first account to refer to the locality of the cases described and his paper first drew general attention to the disease and for this he deserves the credit which he has received. Various alternative names have been suggested for the disease, of which perhaps the best is chronic progressive chorea, but popular usage, a very cogent factor in matters of nomenclature, has stereotyped Dr. HUNTINGTON'S name in connexion with the disease, and Huntington's chorea it will probably remain until a rational and universal system of nomenclature is evolved. Several other papers are devoted to the historical aspects of the disease and Dr. F. TILNEY refers to one family in which the chorea strain may be traced back to colonial Connecticut, giving a known line of descent of nearly 200 years. Dr. S. E. JELLIFFE gives a preliminary report of his investigation into the relationship of the various American groups of cases to one another. He describes three groups: the first, the Long Island, or Easthampton group; the second, the Bedford group in Bedford, Westchester County, New York; and the third, the Wyoming group. The "HUNTINGTON Number" contains also a paper by the editor, Dr. WILLIAM BROWNING, on the general distribution of the disease; he states that the disease has been described in every country in Europe (with the possible exceptions of Turkey, Norway, and Sweden), in the West Indies and South America, as well as Canada, and in all parts of the United States. There is no known colour or racial difference, since cases have been recorded in negro families. The pamphlet concludes with a very useful bibliography extending to more than 200 references. This is a very interesting and valuable work and the editor is to be congratulated upon its production.

◆

Medical Remuneration.

IF Wisdom be justified of her children it is not to be doubted that the "silly season" may in like manner be justified of hers, or that her presence with us this year has been adequately signalised by an exceptionally foolish correspondence, conducted not only in the columns of our esteemed contemporary the *Daily Telegraph*, but also in those of journalism of a less distinguished and responsible kind. The subject of discussion has been the right of medical practitioners to refuse their services to persons unable or unwilling to pay for them—a right which at first glance would appear to be not only unquestionable, but to rest upon the elementary principles of honesty expressed in that utterance of the highest authority which pronounced the labourer to be worthy of his hire. The text of the correspondence was furnished by the report of an inquest held last month by Mr. SCHRODER on the body of a man found bleeding by his landlord, who thereupon "hurried to a medical man" and was told by him that he would not attend unless his fee of 5*s.* were first paid. The witness refused to be responsible for the payment, the medical man did not go, and the patient, who had cut his own throat, was conveyed by the police to a hospital, where he ultimately died. The coroner sensibly observed that "of course" medical men are not bound to attend without payment, and added that he had recently been told of one who had attended 23 cases of supposed emergency without first demanding his fee, with the result that he had received it in respect of only two of the number. In the particular case before the coroner the emergency did not appear to have been very great, for the man lived to be taken to a hospital as described and ultimately died there from delirium tremens. A verdict was returned in accordance with the evidence, and so the matter would have rested had it not been for the gush of letter-writing which it called forth. Among the writers was Miss E. N. DAVIES, who drew a curious and quite imaginary parallel between a medical man summoned to a case of attempted suicide and a miner summoned to assist at the rescue of comrades from a pit. Miss DAVIES was unable to perceive that the miner goes to the aid of his comrades because he is liable to be himself in similar straits at any time, and thus to require from them help of the same kind as that which he is ready to render. She also misstates the case in saying that the appeal to the medical man was made by a "friend" of the patient instead of by his landlord. It appeared from the evidence that the "friendship" was at least not sufficient to bear the strain of a demand for 5*s.*, and it may fairly be assumed that if the messenger, whether friend or landlord, felt no assurance of being repaid to this extent, the medical man was fully justified in a similar degree of scepticism. Miss DAVIES, however, was not the only person impelled to write upon the subject; and a correspondence has ensued which, among other things, has borne striking testimony to the general benevolence and charity of the members of our profession.

The fact nevertheless remains that this benevolence and charity, which we should grieve to see curtailed in their application to proper objects, have for many years been so systematically abused that there would be considerable justification for a very resolute stand against the light in which the payment of medical men has come to be regarded by large sections of the public. Of the nature of this light there is abundant evidence in the correspondence to which we have referred. It is plain that medical men have so accustomed the public to regard illness as an "emergency," in which the sufferers are morally entitled to aid from *the first* person at hand who is competent to render it, that the correlative title of the helper to his remuneration has to a certain extent been suffered to pass out of sight or, at all events, to be regarded only as a secondary consideration. There are, no doubt, circumstances in which this view might be justified, as in serious accidents involving many people and in which the first thing to be thought of would be the rescue of the sufferers or the treatment of the injuries which they had sustained. The view, *nevertheless*, is quite inapplicable to the ordinary events of illness or to the ordinary calls which are made upon the time and attention of practitioners. Real emergencies, conditions

success can quickly be changed to failure. My experience of public boards in Dublin leads me to think that it is very easy for a medical man who happens to be a member of such a board to induce his colleagues to undertake considerable sanitary reforms if they are satisfied he is acting unselfishly. Thus, the South Dublin board of guardians has erected, on my motion, a well-equipped tuberculosis hospital under Dr. Dunne, and the Dublin corporation has also, on my initiative, determined to devote the product of 1*d.* in the pound out of the rates every year on a sanatorium, for which a site has already been selected. But members of such boards are prone to suspicion, and it is difficult to assure them that a practitioner is entirely unbiassed if he advocates a system of notification which will put half-crowns in his pocket, whilst it impales for life the person notified.

I am, Sir, yours faithfully,
J. C. McWalter, M.D. Brux., M.A.,
F.F.P.S. Glasg., D.P.H.,
Dublin, Sept. 13th, 1908. Alderman, *City of Dublin.*

IS COWPER FORGOTTEN?

To the Editor of The Lancet.

Sir,—A few weeks ago, by the courtesy of the press, I invited subscriptions to a fund to enable the committee of the Cowper and Newton Museum, Bucks, to place that memorial of the poet and his friend upon a substantial basis. We need about £2500, and the newspapers of the United Kingdom, of the Colonies, and the United States of America have been most kind in their hospitality. Up to the present time we have received £3 in subscriptions. One may well ask, Have we forgotten Cowper, the gentle poet, the author of "John Gilpin," "The Task," and of so many beautiful hymns, including "God moves in a mysterious way" and "Hark, my soul! it is the Lord"? We are not disheartened yet; we are waiting for the English-speaking people of the world to come forward and provide this modest sum of money.

The secretary is Mr. Thomas Wright, to whom subscriptions should be addressed. His address is The Cowper and Newton Museum, Olney, Bucks.

I am, Sir, yours faithfully,
John Collingridge.
Aldersgate-street, London, E C., Sept. 9th, 1908.

CONTROL OF DISINFECTANTS.

To the Editor of The Lancet.

Sir,—Our attention has recently been called to the fact that in several of the tender forms calling for supplies of disinfectants issued by medical officers of health, among them those of the City of London and the borough of Holborn, one of the conditions imposed requires that the disinfectant *shall not separate out on standing.* We wish to draw the attention of your readers to the indefiniteness of such a condition, although we agree that it is very important, in the interests of public health, that disinfectants should, when mixed with water, form a permanent emulsion, especially as in many cases the disinfectant solution is kept for some time before use.

In many of the disinfectant emulsions commonly used in this country the active ingredient will separate out on standing under certain conditions of time, temperature, and dilution. In our several laboratories we have endeavoured to ascertain the relative value of disinfectants from this point of view by taking the precaution of making the test, which is known under our names, on 1 per cent. solutions or emulsions of the disinfectant after such dilution has been allowed to stand for 24 hours prior to the test being made, and we therefore venture to suggest that in order to insure uniformity of result our practice should be followed by other workers—viz., that before applying the Rideal-Walker test to a disinfectant a 1 per cent. solution should be prepared at normal temperature in an ordinary one-mark stoppered litre flask, such as is used in volumetric analysis, the portion required for further dilutions in the test to be pipetted from the top of the flask after 24 hours' subsidence, avoiding the withdrawal of any insoluble matter which may be floating on the surface.

We are, Sir, yours faithfully,
Samuel Rideal.
J. T. Ainslie Walker.
Chemical Laboratory, Victoria street, Westminster, S.W.,
Sept. 9th, 1908.

A RECENT ALTERATION IN THE MEDICAL DIRECTORY.

To the Editor of The Lancet.

Sir,—The receipt of the usual slip sent out annually for correction by the editors of the Medical Directory prompts me to ask for a little of your space in order to protest against a recent alteration (made I think for the first time last year) which to my mind is far from being an improvement. I refer to the "Local List" for London which follows the alphabetical list of names. Formerly the names in this local list were given under the streets with, I fancy, the numbers of the houses. Now, I suppose with the idea of saving space, the names are given in many instances under districts—e.g., Camberwell—without any indication of the streets or numbers. With regard to the streets there does not seem always to be a very definite plan. It is surely absurd that the name of Dr. A who resides in Devonshire-*street* should be found under that street whilst if one seeks for Dr. B who lives in Devonshire-*place* it is practically impossible to find him, Devonshire-place being omitted. It is true that the name is entered *under Portland-place* but how can one possibly guess such a conundrum? Again the massing together of names under districts is most inconvenient—indeed, practically useless. I beg you, Sir, to use your influence to persuade the publishers of this otherwise most useful work to return to their former arrangement.

I am, Sir, yours faithfully,
Sept. 13th, 1908. Non Œdipus

A QUESTION OF SOBRIETY.

To the Editor of The Lancet.

Sir,—I am sorry to find myself at variance with so distinguished a physician as Dr. C. A. Mercier[1] as regards the different influences of drink on sober and drunkard.

Most people would, I suppose, call me sober—I hardly ever touch intoxicating liquor except with the definite intention to be sociable. I keep a good whisky and a tolerable port in case any friends drop in, but I do not suppose I have got through a bottle of whisky this year by myself. It was not ever thus. 15 or 20 years ago I drank as much as my neighbours and liked it—I found it increased sociability at the time but impaired work afterwards. I found that the more alcohol I drank the more I wanted to drink—one split or one cocktail was very little good, it only wetted the palate and whetted the thirst for another. Further, the expense I found considerable. So to my very great regret I concluded I had to give up drink almost altogether and I did do, swayed not by inclination but by prudence. I cannot assign myself to the class mentioned by Dr. Mercier who cannot get drunk if they try, and this although I have never tried. A cousin of mine might at one time have been almost described as a drunkard. His own self-control was not enough to keep him straight, but he married and his wife reinforcing his self-control he is now undoubtedly sober. I venture to think that Dr. Mercier's is one of those hypotheses which may do great harm and should not be sown broadcast till they are completely proved. It is much safer to preach to the drunkard that the fault is in his own weakness and that heaven helps those who help themselves. Somewhat naturally, I do not sign my name.

I am, Sir, yours faithfully,
M.D.
August 27th, 1908.

---

[1] The Lancet, August 8th, 1908, p. 411.

The Devon County Council and the Medical Inspection of School Children.—At a meeting of the Devon county council held on Sept. 11th it was decided to adopt the resolution of the education committee and to appoint three medical inspectors of school children at a salary of £250 per annum each, with reasonable travelling and hotel expenses. The successful candidates will be required to devote the whole of their time to the duties and to work under the supervision of the county medical officer of health. An amendment was moved to the effect that the education committee should ascertain whether the medical officers of health in the county would undertake the work, but this was defeated by a large number of votes.

man and in a few mileage is considered. Richmond's offer of 1½ guineas for every case is perhaps the most satisfactory. The Bromley union, on the other hand, offers only 10*s.*, the fee which its district medical officers now receive. The circular prompted the Risbridge guardians to write to the Local Government Board urging that it would be better for both patients and medical men if an Order were to be issued making the guardians responsible for the payment of the fee fixed by Order, and giving them power to recover it from the husband or natural guardian of the woman in suitable cases. Taking the replies as a whole, they indicate that the boards of guardians of the country are at least leavened with the principles of equity in this matter, and we hope to see many more take the action which is legally open to them and thus obviate a grave injustice to medical practitioners and to indigent mothers. Medical men practising in unions the guardians of which refuse to accept the responsibility of paying them fees for arduous services are liable to be attacked for inhumanity if they refuse to attend a pauper on a midwife's summons, or to go entirely unrewarded if they spend the best part of a night in anxious and devoted attendance. We are in general agreement with the recommendations of the Midwives Committee of the London and Counties Medical Protection Society on the receipt of these replies. They run as follows :—

1. That it should be clearly understood that no doctor shall be expected to attend on the summons of a midwife unless he chooses to undertake such work at the fees guaranteed by the guardians, or others.

2. That the fees of doctors summoned by midwives should be paid to them in all cases without requiring from them any proof of the poverty of the patients, any necessary inquiry being made by the boards of guardians, or others, who should pay the fees of the medical practitioners without demur, and then take such steps as they might think fit to recover the fees when the patients are able to pay them.

3. That when a doctor is summoned by a midwife to operate or attend on a woman in a serious emergency he should be the judge as to whether or not he should visit the patient again, and, if so, how often, and that for these visits the doctor should be entitled to the usual fees in addition to the fee for the operation or attendance.

These resolutions were adopted by the council of the society on Sept. 2nd, together with other recommendations, the chief of which fixes the fee of 1 guinea as the lowest that should be received by a medical practitioner for attendance on a confinement case and suggests that not less than double this amount should be paid in cases of special difficulty.

THE EYESIGHT OF SCHOOL CHILDREN.

WE publish in another column some interesting statistics of the defects of vision found in the children attending certain army schools in India. If confirmation were needed they emphasise the importance of such investigations. Indeed, where education is compulsory a proper regard for the hygienic conditions under which it is carried out becomes a duty which can no longer be ignored. The trend of modern medicine is more and more in the direction of prophylaxis and it cannot be doubted that in the future the medical inspection of school children will be greatly extended in scope. The problem has already occupied much attention by the London County Council. The advice of their education sub-committee has not yet been confirmed nor have definite steps been taken to put it into practice. It is to be hoped that there will be no undue delay, for the ophthalmic hospitals and departments of London are again being flooded with refraction cases from the Council's schools. Special attention may be directed to the suggestion in the report which we publish that the eyes of all children should be examined by a medical officer for early signs of squint and other visual defects before school attendance is commenced. Though this may be a counsel of perfection where large masses of the poorer classes are concerned, general practitioners might with advantage take note of it. The amount of pain and discomfort which might be spared by a periodic examination of children's eyes, teeth, and general health is patent to every medical man, but is far too little appreciated by the public at large.

SPASTIC CONSTIPATION.

THE condition of spastic constipation, or spastic obstipation as it is often called by German writers, is one which has not received the attention in this country which its frequency warrants, the more so that its treatment is entirely different from that of the ordinary or atonic form of constipation. We have received a paper from Dr. Gustav Singer, a translation of his article in the *Wiener Klinische Wochenschrift*, giving an interesting account of this condition. He states that its recognition has only been comparatively a recent matter and he refers to a paper by Cherchevsky, published in 1883, as giving an account of six cases. Cherchevsky recognised that aperients tended to aggravate the condition and that relief could be afforded by opiates and belladonna. Fleiner, Hackel, Kraus, and Westphal all made observations on cases of this type. Dr. Singer, in recording his own observations, differentiates two forms of spastic constipation, a symptomatic variety occurring in association with diseases of the intestines or other abdominal organs, and an idiopathic or nervous form occurring in association with neurasthenia, hysteria, and other conditions of the nervous system and in some persons independently. The symptomatic form occurs not only in connexion with local lesions of the intestine but also with chronic disease of the internal genital organs of women, with chronic disease of the prostate in men, and with local disease of the rectum, such as fissure, hæmorrhoids, and proctitis, in both sexes. A similar condition is said to be a constant association of nephritic colic and to be not infrequent in cases of hyperchlorhydria. The symptoms of spastic constipation differ widely in different cases, and many of them are the result of the coincident dyspepsia and neurasthenia. In regard to defæcation the patients complain of the defective action of the bowels and usually notice that the amount evacuated is very small. The act of defæcation is associated with great straining and exertion. There is frequently a false desire, causing ineffective attempts to effect the emptying of the bowels. The patients often complain that they can feel the fæcal matter in the intestine but are unable to void it, or they sometimes have frequent small evacuations at short intervals—a condition which is termed "fragmentary evacuations" by Boas. This is compared to frequency of micturition by Dr. Singer. On examination the abdomen is often found to be in a scaphoid condition, and on palpation sections of the large intestine may be found to be contracted to form cord-like masses. Sometimes the descending colon may be felt as a firm, sausage-shaped, cylindrical body, sensitive to pressure. More rarely the same condition may be felt in the right iliac fossa, but as a rule the cæcum is felt as an inflated, pear-shaped, elastic body. These areas of contraction may be felt to alter in position and may be noticed in one part of the large intestine at one time and at another part on a subsequent examination. Dr. Singer states that the obstruction to the passage of the fæces may be so marked as to simulate intestinal obstruction—a condition which has been called by Leube "ileus spasticus." It is always important to examine the rectum in these cases; in purely nervous cases no local condition is found sufficient to account for the symptoms. On using a bougie, after overcoming the resistance of the external sphincter and passing on the bougie a ring-shaped obstruction is encountered, the contracted internal sphincter, which Dr. Singer regards as the site of the chief contraction

success can quickly be changed to failure. My experience of public boards in Dublin leads me to think that it is very easy for a medical man who happens to be a member of such a board to induce his colleagues to undertake considerable sanitary reforms if they are satisfied he is acting unselfishly. Thus, the South Dublin board of guardians has erected, on my motion, a well-equipped tuberculosis hospital under Dr. Dunne, and the Dublin corporation has also, on my initiative, determined to devote the product of 1*d.* in the pound out of the rates every year on a sanatorium, for which a site has already been selected. But members of such boards are prone to suspicion, and it is difficult to assure them that a practitioner is entirely unbiassed if he advocates a system of notification which will put half-crowns in his pocket, whilst it impales for life the person notified.

I am, Sir, yours faithfully,

Dublin, Sept. 13th, 1908. Alderman, City of Dublin.

IS COWPER FORGOTTEN?

To the Editor of THE LANCET.

SIR,—A few weeks ago, by the courtesy of the press, I invited subscriptions to a fund to enable the committee of the Cowper and Newton Museum, Bucks, to place that memorial of the poet and his friend upon a substantial basis. We need about £2500, and the newspapers of the United Kingdom, of the Colonies, and the United States of America have been most kind in their hospitality. Up to the present time we have received £3 in subscriptions. One may well ask, Have we forgotten Cowper, the gentle poet, the author of "John Gilpin," "The Task," and of so many beautiful hymns, including "God moves in a mysterious way" and "Hark, my soul! it is the Lord"? We are not disheartened yet; we are waiting for the English-speaking people of the world to come forward and provide this modest sum of money.

The secretary is Mr. Thomas Wright, to whom subscriptions should be addressed. His address is The Cowper and Newton Museum, Olney, Bucks.

I am, Sir, yours faithfully,
JOHN COLLINGRIDGE.
Aldersgate-street, London, E.C., Sept. 9th, 1908.

CONTROL OF DISINFECTANTS.

To the Editor of THE LANCET.

SIR,—Our attention has recently been called to the fact that in several of the tender forms calling for supplies of disinfectants issued by medical officers of health, among them those of the City of London and the borough of Holborn, one of the conditions imposed requires that the disinfectant *shall not separate out on standing.* We wish to draw the attention of your readers to the indefiniteness of such a condition, although we agree that it is very important, in the interests of public health, that disinfectants should, when mixed with water, form a permanent emulsion, especially as in many cases the disinfectant solution is kept for some time before use.

In many of the disinfectant emulsions commonly used in this country the active ingredient will separate out on standing under certain conditions of time, temperature, and dilution. In our several laboratories we have endeavoured to ascertain the relative value of disinfectants from this point of view by taking the precaution of making the test, which is known under our names, on 1 per cent. solutions or emulsions of the disinfectant after such dilution has been allowed to stand for 24 hours prior to the test being made, and we therefore venture to suggest that in order to insure uniformity of result our practice should be followed by other workers—viz., that before applying the Rideal-Walker test to a disinfectant a 1 per cent. solution should be prepared at normal temperature in an ordinary one-mark stoppered litre flask, such as is used in volumetric analysis, the portion required for further dilutions in the test to be pipetted from the top of the flask after 24 hours' subsidence, avoiding the withdrawal of any insoluble matter which may be floating on the surface.

We are, Sir, yours faithfully,
SAMUEL RIDEAL.

A RECENT ALTERATION IN THE MEDICAL DIRECTORY.

To the Editor of THE LANCET.

SIR,—The receipt of the usual slip sent out annually for correction by the editors of the Medical Directory prompts me to ask for a little of your space in order to protest against a recent alteration (made I think for the first time last year) which to my mind is far from being an improvement. I refer to the "Local List" for London which follows the alphabetical list of names. Formerly the names in this local list were given under the streets with, I fancy, the numbers of the houses. Now, I suppose with the idea of saving space, the names are given in many instances under districts—e.g., Camberwell—without any indication of the streets or numbers. With regard to the streets there does not seem always to be a very definite plan. It is surely absurd that the name of Dr. A who resides in Devonshire-*street* should be found under that street whilst if one seeks for Dr. B who lives in Devonshire-*place* it is practically impossible to find him, Devonshire-place being omitted. It is true that the name is entered under Portland-place but how can one possibly guess such a conundrum? Again the massing together of names under districts is most inconvenient—indeed, practically useless. I beg you, Sir, to use your influence to persuade the publishers of this otherwise most useful work to return to their former arrangement.

I am, Sir, yours faithfully,

A QUESTION OF SOBRIETY.

To the Editor of THE LANCET.

SIR,—I am sorry to find myself at variance with so distinguished a physician as Dr. C. A. Mercier[1] as regards the different influences of drink on sober and drunkard.

Most people would, I suppose, call me sober—I hardly ever touch intoxicating liquor except with the definite intention to be sociable. I keep a good whisky and a tolerable port in case any friends drop in, but I do not suppose I have got through a bottle of whisky this year by myself. It was not ever thus. 15 or 20 years ago I drank as much as my neighbours and liked it—I found it increased sociability at the time but impaired work afterwards. I found that the more alcohol I drank the more I wanted to drink—one split or one cocktail was very little good, it only wetted the palate and whetted the thirst for another. Further, the expense I found considerable. So to my very great regret I concluded I had to give up drink almost altogether and I did do, swayed not by inclination but by prudence. I cannot assign myself to the class mentioned by Dr. Mercier who cannot get drunk if they try, and this although I have never tried. A cousin of mine might at one time have been almost described as a drunkard. His own self-control was not enough to keep him straight, but he married and his wife reinforcing his self-control he is now undoubtedly sober. I venture to think that Dr. Mercier's is one of those hypotheses which may do great harm and should not be sown broadcast till they are completely proved. It is much safer to preach to the drunkard that the fault is in his own weakness and that heaven helps those who help themselves. Somewhat naturally, I do not sign my name.

I am, Sir, yours faithfully,
M.D.

[1] THE LANCET, August 8th, 1908, p. 411.

THE DEVON COUNTY COUNCIL AND THE MEDICAL INSPECTION OF SCHOOL CHILDREN.—At a meeting of the Devon county council held on Sept. 11th it was decided to adopt the resolution of the education committee and to appoint three medical inspectors of school children at a salary of £250 per annum each, with reasonable travelling and hotel expenses. The successful candidates will be required to devote the whole of their time to the duties and to work under the supervision of the county medical officer of health. An amendment was moved to the effect that the education committee should ascertain whether the medical officers of health in the county would undertake the work, but this was defeated by a large number of votes.

similar congress at Middlesbrough some six years ago. Since that time further expert evidence against the offender has been brought from various bacteriological laboratories and sanitary authorities. "And with this evidence available," said Sir James Crichton-Browne, "I do not believe that any scientific jury will hesitate to find the fly guilty as a carrier of disease," an assertion in which we thoroughly agree with him as those who have followed our columns of recent years will remember. Other outstanding matters dealt with in his address, which was entitled "Liverpool Sanitation, Disease Carriers," were the splendid health work carried out of recent years in Liverpool by Dr. E. W. Hope and his colleagues—work which Sir James Crichton-Browne described as "colossal"—tuberculous disease, alcoholism, the housing problem, human typhoid carriers, and books as spreaders of disease. A natural transition led him from the consideration of the danger to the body of library books exposed to infection, to the even greater and more insidious danger to the mind of a certain limited class of pornographical printed matter which unfortunately commands a ready sale in this country. With this disquieting problem of mental hygiene Sir James Crichton-Browne concluded his very comprehensive address, which we trust has been read and pondered in many thousands of households. Other papers read at the Congress were on "Sanitation in Ancient Greece," by Dr. R. Caton, Lord Mayor of Liverpool; "The Sanitary Administration of Liverpool," by Mr. W. Muirhead, chairman of the Liverpool sanitary sub-committee; "Organised Endeavour against Diseases, or Lessons to be Learnt from the Health Campaign in Ireland," by Sir Rubert W. Boyce, F.R.S., Liverpool University; "Housing and Town Planning," by Dr. A. A. Mussen, assistant medical officer of health of the city of Liverpool; and "Health and the Home," by Mr. A. G. Duck, chief sanitary inspector, Woolwich. The business of the Incorporated Sanitary Association of Scotland, which assembled in Congress on Sept. 3rd at Peebles, under the presidency of Dr. Charles Templeman, medical officer of Dundee, included an address from the chair on "The State and the Individual in Eugenics," and papers on "The Mental Hygiene of Childhood," by Dr. J. R. Watson and Mr. M. Ritchie, B.Sc.; on "The Cleansing and Disinfecting of Schools," by Dr. T. F. Dewar; on "Housing and Town Planning," by Mr. F. G. Holmes; on "Waterworks Administration," by Mr. W. A. Tait; on "A Proposed Territorial System of Fighting Consumption," by Dr. T. F. S. Caverhill; and on "The Dangers in the Milk-supply," by Dr. G. M. Cullen, Dr. A. Campbell Munro, and Mr. John Findlay. A discussion on "The Problem of the Unemployable," opened by Mr. Andrew M'Crachen of Glasgow, also formed part of a busy two days' programme, which attracted a fair share of attention in the Scottish press.

RHUS TOXICODENDRON.

Sir E. Ray Lankester, in directing attention to the poisonous effects of rhus toxicodendron or "poison ivy," has caused widespread and unnecessary alarm among uninstructed folk. As a result many suspected specimens of various garden plants have been sent to botanical authorities for identification. In one case the harmless ampelopsis, a favourite suburban climber, was mistaken for "poison ivy" by a medical man who advised the owner and others having similar plants to have them destroyed. In view of the possibility of mistakes of this kind recurring Mr. E. M. Holmes, curator of the museums of the Pharmaceutical Society, has published[1] a description of the plants. There are three forms of ampelopsis, one of which is the ordinary virginian creeper. They are distinguishable from rhus toxicodendron in that the latter never has tendrils and the terminal leaflet always has a longer stalk than the two side leaflets. The creeper on the walls of gardens having three leaflets with stalks of equal length and provided with tendrils may therefore be regarded as perfectly harmless. The typical rhus toxicodendron is an erect shrub, but there exists a climbing variety in cultivation. Like many other plants of the same family, it contains an acrid juice which blackens on exposure to air. It has a most irritating effect on persons of an erysipelatous tendency or whose skin is particularly sensitive to the bites of gnats and fleas. To such persons the plant is really dangerous, causing a painful dermatitis that in some cases recurs annually. The irritating action has been variously ascribed to acetic acid, a volatile acid substance, a volatile alkaloid, and a non-volatile oily body named toxicodendrol. The fact that some people are affected by proximity to the plant without actually coming in contact with it points to the probability that a volatile constituent is the cause of the poisonous action. Several remedies have been employed with varying success, including the tinctures of lobelia and serpentary and the fluid extract of grindelia. Most relief is probably to be obtained by using an alcoholic solution of lead acetate as a lotion, with the addition of tincture of opium to allay the pain. Rhus toxicodendron is not described in Bentham and Hooker's "British Flora," and there is but a remote chance of trouble arising in the British Isles from contact with the plant. In the United States, on the other hand, where it flourishes, children are cautioned against the plant, especially when rambling in the woods. In cases of poisoning by the "poison ivy" vomiting, drowsiness, stupor, dilated pupils, convulsive movements, delirium, and fever have been observed. Homœopathists have largely employed a tincture of the plant in subacute and chronic rheumatism, but Dr. H. C. Wood some years ago gave it an extended trial in the Philadelphia Hospital and was unable to perceive that the patients progressed more rapidly when taking the drug than when they were simply nursed.

THE NORTHERN INFIRMARY, INVERNESS.

WE have received a somewhat belated account of the position of affairs existing at the Northern Infirmary, Inverness, a position brought about by the action of the committee of managers. The meeting was held on August 28th and resulted in an alteration being made in Rule 17 of the constitution of the infirmary. The rule used to read as follows:—

> The medical staff shall consist of consulting members and not more than four acting and two assistant members, to be appointed by the managers at the annual general meeting in May, or at a special general meeting to be called for the purpose. The consulting members shall be appointed out of those who are or who have been members of the acting staff, during the pleasure of the managers. The appointment of the acting members shall be for a period of five years, and thereafter during the pleasure of the managers until each shall have served 15 years. On a vacancy occurring among the acting members the vacancy shall be filled up by the appointment of one of the assistant members. No member of the acting staff shall continue to hold office after attaining the age of 60 years, unless the managers shall see cause to continue his appointment.

As amended, the number of acting members is increased to five and power is given to the managers, in the event of a vacancy occurring among the acting members of the medical staff, of passing over the assistant members and of appointing any qualified medical man. As a result of the amendment of the rule the following curious position was arrived at. Dr. A. W. Mackay, who had served for 15 years on the acting staff, was for that reason compulsorily retired, and in the natural course of events would have been elected a member of the consulting staff. The senior assistant medical officer, Dr. Gordon A. Lang, was appointed to fill the vacancy caused by Dr. Mackay's retirement,

success can quickly be changed to failure. My experience of public boards in Dublin leads me to think that it is very easy for a medical man who happens to be a member of such a board to induce his colleagues to undertake considerable sanitary reforms if they are satisfied he is acting unselfishly. Thus, the South Dublin board of guardians has erected, on my motion, a well-equipped tuberculosis hospital under Dr. Dunne, and the Dublin corporation has also, on my initiative, determined to devote the product of 1*d.* in the pound out of the rates every year on a sanatorium, for which a site has already been selected. But members of such boards are prone to suspicion, and it is difficult to assure them that a practitioner is entirely unbiassed if he advocates a system of notification which will put half-crowns in his pocket, whilst it impales for life the person notified.

---

[1] THE LANCET, August 8th, 1908, p. 411.

had been floating about among theoretic physicians for some centuries before Galen, but it was he who put it into dogmatic shape, and it pretty well held the field down to the seventeenth century." The theory of Alkhendi is chiefly interesting in showing the way in which the early physicians sought to set prescribing on a scientific basis. His formula appears ludicrous when viewed in the light of modern knowledge, but the use of formulæ may again be adopted when *the study of pharmacology has shed more light* on the quantitative action of drugs. The power of calcium chloride to increase the coagulability of the blood affords an illustration of a drug that is capable of yielding very definite results and the researches of Wright and others are showing clearly its possibilities and its limitations. It is possible to determine the necessary dose of this salt by ascertaining the amount of calcium already present in the blood, and this clearly shows the way to a mathematical method of prescribing.

CICATRICIAL STENOSIS OF THE COMMON BILE-DUCT: IMPLANTATION AT ANOTHER POINT IN THE DUODENUM.

IN the *Boston Medical and Surgical Journal* of July 23rd Dr. Horace Packard has reported the following case which *illustrates* a new operation in plastic surgery. In February, 1907, he saw a man suffering from profound jaundice. Three years previously he had an attack of jaundice from which he recovered. A month previously he again became jaundiced with an attack of influenza. The stools were clayey and the urine very dark. Later the stools became very black and were still so. There had been pain in the epigastrium and right hypochondrium. In the right *hypochondrium* an elongated oval tumour, extending from the eighth costal cartilage to below the level of the umbilicus, was felt. It was evidently the gall-bladder. Plugging of the common bile-duct by a calculus was diagnosed. The gall-bladder was exposed. It was enormously distended and thinned to the point of rupture and showed degenerative spots suggesting impending perforation. Cholecystectomy was deemed imperative and performed. No calculi were found in the gall-bladder. The cystic duct was doubly ligatured close to the common duct. The common duct was palpated and found greatly distended, but no stone could be *detected*. It was slit open and a small drainage-tube was inserted and fastened in with catgut. As the condition of the patient was precarious it was deemed unwise to prolong the operation, although the cause of the obstruction had not been removed. In the next four weeks the jaundice gradually disappeared. The stools became white. Bile poured from the wound day and night. At the same time the patient developed a ravenous appetite. Under these favourable conditions it was hoped that the common duct would become opened, but after eight weeks there was still no bile in the stools. On April 11th the wound was reopened and the biliary sinus was traced down to the common duct. The duodenum was exposed by incising the peritoneum at its reflexion on to the posterior abdominal wall and opened to admit the finger to explore the ampulla of Vater, where a deep ulcer surrounded by inflammatory tissue was found. The *difficult* problem arose of restoring communication between the common duct and the duodenum. Dr. Packard knew of no precedent, but he further isolated the common duct from its surrounding attachments and cut off its duodenal end. He had a little over an inch of duct free. He punctured the duodenum at a point favourable *for implantation*, and with the aid of two Pagenstecher threads passed through the duct and serving as leaders, pulled it through the opening until it could be seen well inside the mucous membrane. The threads were used to fasten the duct to the mucous membrane. With a continuous Pagenstecher thread the muscular wall of the gut was folded over the duct. The incision in the duodenum was then closed. In view of the pathological condition in the duodenum it was deemed wise to perform posterior gastro-enterostomy. Drainage was provided for at the point of implantation and the wound was *closed*. *The* leakage of bile ceased and the fæces resumed their normal colour *in a few days*. The wound suppurated but healed rapidly by granulation. For the first few days the patient was fed per rectum. Convalescence was rapid and he completely recovered his health, though he had some pain in the right hypochondrium after a full meal. Dr. Packard thinks that the presence of the black stools (melæna) should have led him to the diagnosis of ulcer of the ampulla of Vater causing obstruction of the common bile by cicatricial contraction. A curious fact, difficult of explanation, is that the cicatricial contraction of the ulcer of the ampulla did not cause obstruction of the pancreatic duct. Only two similar operations appear to have been recorded in the United States. Dr. W. J. Mayo *successfully implanted* the hepatic duct in the duodenum. Dr. F. B. White and Dr. F. B. Lund have reported a case of excision of the pylorus and first portion of the duodenum in which the common duct was cut and successfully implanted in the second portion of the duodenum.

PROTRUSION OF THE SMALL INTESTINE PER ANUM: A RARE CASE.

WOUNDS or ruptures of the rectum are, apart from obstetric cases, by no means common, and those which permit the passage of portions of small intestine to enter the rectum and even to protrude from the anus are of extreme rarity. Dr. Enrique Zarate has just published in *La Semana Médica* a case of this kind which he treated successfully in the Fernandez Hospital, Buenos Ayres. A woman, aged 29 years, while *going upstairs* slipped and fell backwards. She felt an acute pain in the abdomen and almost immediately *afterwards* lost consciousness. When taken to the hospital she was in a state of semi-collapse. About two metres of small intestine with the corresponding mesentery were seen to be *emerging* from the anus and there was complete prolapsus uteri. This latter condition was due to a perineal rupture *during* instrumental delivery seven years previously. The patient had always been able to replace the uterus without assistance, so no difficulty was found in that part of the operation. The fan-shaped bunch *of small* intestine it was found impossible *to* reduce, and so laparotomy was performed, Trendelenburg's position being employed. The bladder was greatly hypertrophied. There were some coagula in the pelvis and on raising the uterus a rupture was found in the anterior wall of the rectum extending from opposite the fundus *of the pouch* of Douglas upwards for 10 or 12 centimetres, though the whole of the coats of the rectum were only torn through for some 7 or 8 centimetres. The patient made a good, though slow, recovery. She, however, utterly refused to allow the prolapsus uteri to be treated. M. Quénu of the Hôtel Dieu, Paris, *published* two cases of rupture of the rectum with hernia of the small intestine, both the result of excessive *straining* at stool, one occurring in a woman aged 70 years, the other in a man aged 45 years. Sir Benjamin Brodie *performed* laparotomy in St. George's Hospital in 1827 on a young woman who had experienced a sudden pain at night which she fancied betokened an abortion but which was followed by a protrusion of two yards of small intestine from the anus. A transverse tear was found in the anterior wall of the rectum. Professor Adelmann of Dorpat operated in 1845 without anæsthetics on an old woman who after seats. They are quite unsuitable for children. ...... Children of the age attending sit with their feet resting on the foot rails of the desk, their elbows spread out, and the head bent over the desk, the child's face when writing being about six inches from the desk. The seats are too high and have no back-rests.

To reduce the height a number of adults' desks have been cut down, but by this means they are not rendered suitable in many respects for children and are too low for the men. In all infants' schools, too, either adults' desks have been cut down or forms are used as desks should the present standard plan of infants' desk not have been supplied. Even if the standard plan desks have been supplied they are so broad as to render it very difficult for a child to reach the ink, and they are unsuitable in some other respects. Kindergarten work cannot be carried out on a sloping desk, hence the use of forms as desks. The seats are moveable and those which have back-rests slope at too great an angle. The whole arrangement is most unsatisfactory and favours the development of squint, myopia, spinal curvature, and other deformities. In India the provision of suitable desks for children and the improvement of the lighting of schools is, if possible, a matter of greater importance than in England, on account of the fact that in India there are so many causes of enfeeblement of health, with consequent weakening of the muscles and tunics of the eye.

The urgent necessity for the provision of a new type of infants' desks and of some form of adjustable desks for adults and elder children, both of whom of necessity have to use the same desks (on account of want of accommodation), has been pointed out. A plan of a suitable infants' desk has been prepared and a specimen of an experimental adjustable desk for adults and elder children has been made and is being reported on.

BOOKS AND TYPE.

Another important subsidiary cause in the deterioration of eyesight of school children was inquired into—namely, the use of small, ill-defined, closely-set type which, even in a well-lighted room, necessitates holding the book at a shorter distance than 12 inches from the eyes. With two very notable exceptions, the type has been found large, distinct, and well spaced. The exceptions are the Bible and Prayer Book. According to Appendix 7 of the "Standing Orders for Inspectors of Army Schools, 1906, Course of Religious Instruction," "...... In every lesson a portion of Scripture will be read, in part by the teacher and in part by the children of Standards VI. and VII." The type of the Bible and Prayer Book at present in use is much too small; the necessity for at once changing these books for ones with larger type has been represented.

GENERAL REMARKS.

The urgent necessity for improving the lighting of our army schools in India and of supplying suitable desks for children has been clearly shown by the reports submitted by the specialists in ophthalmology. The connexion between shortsightedness and schools is intimate; statistics show that the amount of myopia is in direct proportion to the amount of education. "Acquired" myopia is frequently due to the insufficient lighting of schools or to the stooping of children over their books. The present condition of our army schools in India, as regards lighting and desks, undoubtedly favours the development of myopia and deformities. If the lighting of the school room is defective the child to see clearly has to stoop over the desk and to approximate the eyes unduly near the book. It must be remembered that shortsightedness, when once established, is liable to become progressive and to handicap a child seriously in after life. The inspections now reported on have not only resulted in the correction of errors of refraction by the supply of glasses to 80 children, but it is hoped will also result in the remedying of serious defects (summarised below) in the schools. The attendance at school being compulsory, there can be no question as to the moral obligation to light the buildings properly and to supply suitable desks and seats for children.

SUMMARY OF RECOMMENDATIONS.

(*a*) That the lighting of schools be improved.

(*b*) That a new standard plan of infants' desk be adopted for infants' schools.

(*c*) That a certain number of adjustable desks of the pattern used in England be supplied for adults' and elder children's schools. Should the cost of supplying such desks be prohibitive, adjustable desks to be made locally.

(*d*) That all children should have their eyes examined for commencing squint and other defects before beginning school attendance.

(*e*) That the attention of schoolmasters be drawn to their responsibilities in preventing the deterioration of vision in children.

(*f*) That an order be issued and embodied in regulations to the effect that the walls of schoolrooms be colour-washed pale green once a year.

(*g*) That sunshades from clerestory windows on the north side of all schools be removed and that sunshades over other clerestory windows be hinged, so that they may be raised during the winter months.

(*h*) That the Bibles and Prayer Books at present issued to schools be replaced by others with larger type.

THE FRANCO-BRITISH EXHIBITION.

(FROM OUR SPECIAL SANITARY COMMISSIONER.)

TUBERCULOSIS AND THE FRENCH TOURING CLUB.—PEACE AND SCIENCE.—FRENCH DRUGS AND FRENCH GASTRONOMIC DELICACIES.

IN view of the International Congress on Tuberculosis which will meet this month at Washington the exhibit of the French Touring Club commends itself to notice. Unfortunately, this is in no wise so good an exhibit as that made at the Grand Palais of the Champs Elysées when three years ago the same congress met at Paris. On that occasion two rooms were shown. First, there was the old traditional hotel bedroom, with the wooden bed, heavy curtains above, and no free passage of air underneath. Then close up to the head of the bed stood the evil-smelling bed table. On all sides were carpets, heavy window curtains, and stuffed upholstery; in fact, everything seemed combined to facilitate the harbouring of dust and the multiplication of germs. By the side of this stood the sort of room which some 4000 hotels have now installed in response to the pressure brought to bear upon them by the Touring Club. The model room alone is shown at the present Franco-British Exhibition. By itself it fails as an object lesson, for it affords no contrast, nor are there sufficient explanations given; therefore, most persons pass by without understanding. Yet this is a very useful and practical exhibition. The Touring Club recommends its members to frequent such hotels (and affixes its name over the entrance door) as furnish their bedrooms in the manner here shown and instal a sanitary system of drainage. Thus there are painted and washable walls and therefore no wall paper. There are no curtains to the beds, no wooden beds, and the bed table or night commode is done away with. One or two moveable rugs on the polished bees-waxed floor replace carpets and there is no upholstered furniture or heavy window drapery. Thus have the principles of sanitation been taught by the Touring Club and they have greatly contributed to render travelling and the sleeping in strange places much less dangerous than formerly. This is truly an excellent means of waging war against tuberculosis and also many other diseases.

Not far from the Touring Club room the French Minister of Foreign Affairs has an exhibit which covers a large space on the wall and summarises in a most graphic manner the upshot, the genuine practical result, of this and other international congresses, international exhibitions, and international manifestations of the *entente cordiale* that should prevail between all nations. As lovers of science we must of necessity be ardent advocates of peace and no one can contemplate the magnificent exhibit of the French Minister of Foreign Affairs without feeling a glow of satisfaction and hope, for here we have clearly demonstrated that in spite of cynics and pessimists the cause of peace has made gigantic strides. The exhibit consists of a huge map of Europe with lines drawn from capital to capital showing how the nations have established bonds of amity by concluding treaties pledging themselves in case of dispute to resort to arbitration instead of war. Of such treaties there only existed two in 1903. In 1908 no less than 60 treaties of obligatory arbitration had been signed, showing the immense progress of the peace cause in only five years. First on the list stands Great Britain which has concluded 12 such treaties. Next come Portugal and Switzerland with ten parents; those who are admitted during adolescence in consequence of their inability to earn a living; those who are admitted later in life owing to the death of friends who have hitherto looked after them; those who are loafers and vagrants and are driven in by destitution and stress of weather; and lastly, women who have entered to be confined of illegitimate children. It is noticeable that while in the maternity wards only a small number of the women are feeble-minded, yet that the women who are feeble-minded in very many cases have illegitimate children and that at present they are not and cannot be well protected. The evidence of Mr. Bagenal, speaking on this subject, is striking. "Feeble-minded women are particularly open to the seductions of men. They seem to be deficient in will-power and the power of resistance to attacks upon their virtue. In some the moral sense is altogether absent. The consequences we see in the frequency of this class in the lying-in wards of the workhouse. In one workhouse I found five young women all of whom were feeble-minded. Number one was going to be confined and had had two children before; number two had had two children; number three had had two children; number four had had one child; and number five had been confined in the summer and had had three children previously. All these were illegitimate. The cost of these cases is a very great burden on the rate-payers, especially as the children will probably turn out to be feeble-minded also." So also another witness, Miss Skinner, the superintendent nurse of a union infirmary, gave evidence to the effect that a great many girls admitted to lying-in wards were more or less feeble-minded and unfit to look after themselves, but after their recovery they were discharged and went to the bad because no one had the power to protect them against their will.

With respect to the mentally defective in workhouses, the general impression derived from the evidence is that, while they are kindly treated, they are rather being maintained than being thoughtfully considered, and that but little attention is given to their training. For example, there is the evidence of Dr. Pearse in regard to a southern county. The feeble-minded "do a certain amount of routine work in the institution—wood-chopping, gardening, laundry work; many work well, others only under supervision. There is, however, absolutely no recognition of the fact that they need special training. After treatment suited to their requirements they would be able to provide for themselves much better than they do." But, beside the commonly defective nature of the training, the classification in the workhouses is frequently of an undesirable nature. In a workhouse visited by one of the witnesses there were "imbeciles, idiots, and slightly feeble-minded living in wards together, all ages from 14 to 90. Hardly any attempt was made to teach or occupy the children. On the men's side the boys were partially separated from the men, but the accommodation was cheerless and the life of the boys idle and dreary. Slightly feeble-minded children were associated with the saddest, most hopeless idiots. . . . The medical officer was of opinion that the boys were improvable, but would deteriorate under workhouse conditions. A girl of 14, who had made considerable progress at the special school, was associating with a room full of low type imbecile women." The feeble-minded are frequently housed with the aged and infirm, and the latter wishing for quiet and rest find it impossible in a room full of jabbering idiots.

Evidence pours in on all sides of the immense desirability of keeping some further control over higher grade mentally defective. The vagrant class is largely recruited from the ranks of the feeble-minded. The boys are practically unemployable and rapidly pass into the ranks of the nomad population. The feeble-minded men in the workhouses are frequently such as go into the house for the winter and go out for the summer, picking up a precarious and often unlawful livelihood. The same is true for the women. Over and over again women whom it would be most inadvisable to allow out are detained in the workhouse by some form of persuasion. Take as an instance a woman who had had five children, all by different fathers. Of the five, three most degenerate offspring were dead, while the two surviving were in the custody of the guardians. In the workhouse of a large north country town, when the evidence was taken, there were 60 so-called able-bodied women. Of these, according to the views of the medical officers, 39 were of varying degrees of feeble-mindedness, 16 had children, and none of them were able to take care of themselves. There were 60 able-bodied men, and of these the medical officers thought that 23 should be kept under permanent care. Of the women some were persuaded to stay by means of preferential treatment, but it appeared to be a common experience that the younger and more innocent were very apt to be influenced by a depraved woman and then nothing could keep them in. Others, seized with a restless fit, took their discharge and made their next appearance in the maternity wards. As a result of a consideration of the enormous amount of practically unanimous evidence that came before the Commission the opinion is formulated that the accommodation provided for the feeble-minded is insufficient, unsatisfactory, and unsuitable, and that "of late years, with an increased sympathy for those who are suffering from mental weakness and defect, with a closer study of mental science, and with the general application of the principle of educational equality to all classes of children, including the feeble-minded, there has sprung up a demand for a more discriminative and individual treatment of mentally defective persons which cannot but entail a reorganisation of the public provision hitherto furnished for the afflicted."

With regard to the metropolis a very similar tale is told. To begin with the children. Notes of 100 cases of boys and 28 cases of girls, juvenile offenders under 16 years of age, who were placed in the remand home of the Metropolitan Asylums Board, supply illustrative statistics. Out of the boys 37 were graded as between "backward" and "mentally deficient," of the girls 16 out of 28 were so graded. If these proportions are applied to the numbers of children treated as juvenile offenders the question becomes plainly a very serious one. In three years there were 32 girls at the remand home under seven years of age and of these 15 were living with prostitutes. Of girls 13 years of age there were 93, of whom 15 were charged with stealing and larceny, 10 with living with prostitutes, and 36 with wandering. As mentally defective after 16 or later, more than half of these would be likely to come upon the public authorities or on voluntary charity for support. A similar state of affairs obtains among the boys. The home circumstances of 40 such cases were investigated and their vicious and unhygienic character demonstrated. In the 40 cases 35 per cent. of the fathers and 25 per cent. of the mothers were known to have been heavy drinkers. Phthisis was found in 11 fathers and seven mothers. Of the total cases 60 per cent. of the parents were drinkers and 30 per cent. were phthisical. Flagrant immorality was charged against 15 per cent. of the fathers and 47·5 per cent. of the mothers. Of the children 14·9 per cent. were illegitimate, while others had been deserted and might reasonably be supposed also to be illegitimate. Out of 4551 cases submitted to the medical officer to the London County Council with a view to his selecting those children who should be admitted to the special schools for mentally defective children, 1728 were entered as mentally defective and 187 were rejected as imbecile. *For these cases when they reach the age of 16 there is no suitable provision*, yet many of them are at that age incapable of even partial self-support. Evidence that this want of protection in later life is *frequently fatal* is considerable. Many mentally defective persons pass through the prisons. At the Holloway prison *out of* 893 women there on a certain date 83 were of that type, 41 were chronic inebriates, 39 were feeble-minded, and three were insane. It appears then that in the metropolis, as elsewhere, there is a comparatively large class of feeble-minded persons who are not regarded as insane but who certainly cannot be held to be entirely responsible, and who are a cause of great trouble and anxiety to those who have to deal with them. Often these have had no education and their mental defect prevents their being employed even as unskilled labourers, while their moral sense is often very defective. Neither has our present administrative organisation made provision for the education of such as these, nor has it devised any method by which they may, in later life, be adequately looked after. At the present the Metropolitan Asylums Board may not take charge of mentally defective children under five years of age, nor keep them after 21, unless they are certified as idiots or lunatics. Similarly, the education committee of the London County Council, which has opened residential homes for the same time it is seen that much may be brought forward concerning the economic aspects of tuberculosis, adverse industrial conditions, the social control of tuberculosis, early recognition and prevention of the disease, after-care of arrested cases, educational methods and agencies, promotion of immunity, and responsibility of society for tuberculosis. Under this last heading we see there is to be a symposium of representative citizens, social workers, employers, employees, physicians, nurses, educators, and others. The provisional programme for Section VI., though set forth in comparatively few lines, promises to provide as much material for discussion as will any of the others, as here the Congress is invited to discuss "laws and ordinances relating to tuberculosis, especially with reference to infection"; "governmental care of tuberculosis patients in the home, dispensary, sanatoria, tuberculosis farms, camps, &c."; "educational propaganda and scientific research under governmental auspices"; "sanitary measures in the home including disinfection, better housing, ventilation, &c."; "sanitary surveillance over travellers and those engaged in trades and occupations in public buildings, factories, workshops, &c."; "prevention of tuberculosis amongst children and adolescents, including the subjects of heredity, environment, schools, factories, playgrounds, &c."; and "collection of statistics."

To Section VII. some 34 authors have already promised to contribute papers which will deal with the prevalence of tuberculosis among domestic animals, the roads of infection, diagnosis, and the question of resistance to tuberculosis, the methods for the control of tuberculosis in animals applicable in heavily infected herds and districts, and giving if possible the results of operations in different countries and in various states of the United States, the comparative bacteriology and pathology of tuberculosis in animals, the relation of tuberculosis in animals to the public health, including the evidence for and against the transmission of tuberculosis from animals to man, infection of man from animals by association, inoculation, feeding on meat and milk; milk hygiene and meat hygiene, in connexion with the latter the guiding principles and rules by which the meat inspector should be governed in adjudging the carcasses of animals infected with tuberculosis.

We have here food for many and interesting debates and from the distinguished men from various countries whose names appear on the list of those who have promised to attend and to take part in the discussions the outcome of this congress should be at least as suggestive as that of any previous congress, and those who are attending as delegates from this country should have a profitable, though probably strenuous, three weeks of congress work.

The following names should be added to the list already announced of British delegates attending the International Congress on Tuberculosis at Washington, U.S.A.: Professor S. Delépine, Victoria University of Manchester; Mr. J. Patten Macdougall, C.B., Local Government Board of Scotland; Dr. A. Newsholme, Local Government Board of England; Professor William Osler, the University of Oxford, the Lister Institute of Preventive Medicine, and the King Edward VII. Sanatorium; Mr. T. J. Stafford, F.R.C.S. Irel., Local Government Board of Ireland; and Dr. H. E. Symes-Thompson, the Royal Hospital for Diseases of the Chest, City-road, London, E.C.

MANCHESTER.

(FROM OUR OWN CORRESPONDENT.)

Asylum Accommodation.

BOTH the Prestwich and the Chorlton unions are much inconvenienced by the crowded state of the Lancashire asylums. The former have charge just now of five certified lunatics for whom no accommodation can be found, and they have been obliged from time to time to send cases to Middlesbrough, where the charges are much higher than in Lancashire. Provision for increased accommodation is being made, but it seems to take a very long time, and one of the board expressed the opinion that if so disposed the asylum authorities could move much more quickly than they were doing. The Lancashire Asylums Board has decided to charge contributing Poor-law guardians 7*d.* a week more per head than hitherto for the maintenance of their lunatics, and at a meeting of the Chorlton board it was stated that this will mean an addition of £1400 a year to the rates. Although this inconvenience is very real, it is, however, rather alarming to think of the very great extension of costly buildings that is being made for lunatics. At Whalley an asylum is being built to accommodate 2000 patients and an extension is proposed at Whittingham for 700 patients.

Seizure of Damaged Food.

To show the valuable part played by the Manchester port sanitary authority in protecting the people from food unfit for use, it is only necessary to refer to the meeting that took place on Sept. 7th. The report stated that the amount of "foodstuffs" (not an agreeable term and one smacking of foreign origin) seized and condemned at the Foreign Animals' Wharf and the Docks during the last month amounted to nearly 270 tons. It must be said, however, that 264 tons consisted of damaged barley taken from a ship that had gone ashore. This barley was afterwards converted into food for cattle instead of malt for brewing. What effect it has had on the cattle has not been stated.

Overlying: Four in a Bed.

An inquest was held at Colne yesterday touching the death of an infant three months old which shows some unusual features and undesirable overcrowding. The mother said that she was 19, and had had three children, the two still alive being aged three years and 18 months. The eldest child and its grandfather slept in the attic, the father and the second child at the bottom of a bed in another room, while the mother and the baby slept at the top of the same bed. She fed the child at 12.30, then slept till 7.45, when she was roused by the elder baby kissing the younger and noticed that the latter was cold, indeed dead. Dr. A. B. Ritchie, the police surgeon, who had made a post-mortem examination, said that the child had died from suffocation through being surrounded by blankets. The youth of the mother is noticeable. The father seems to have been in work as a fork finisher, so that there was no extreme poverty. The mother said that she was a teetotaller and that her husband was a steady man and had had no drink on the Saturday night. The coroner said it was to be hoped that the Government "would find time to get passed into law the Bill now before Parliament which made it an offence for a child to be found dead in bed with its parents." This hope will be echoed by those who know much of the large infant mortality due to the practice of parents having infants in bed with them.

Medical Bequests.

Mrs. Jane Churton of Chester has left £2000 to the Royal Albert Asylum, Lancaster, and the same amount to the Chester General Infirmary, together with an additional sum of £2400 to the latter institution to endow two beds. She also left £1000 to the Children's Convalescent Home, West Kirby, and £500 to the Convalescent Home, Parkgate. Her medical attendant receives a legacy of £1000. There were many other bequests to charities, religious purposes, and legatees.

Sovereigns for Ashton Babies.

Since Mr. Broadbent set the example at Huddersfield the rewarding (or the bribing) of mothers if they keep their babies alive over the first twelve months has been followed in some few cases In Ashton-under-Lyne the mayor, Colonel J. W. Pollitt, offered to give £100 for distribution among the parents of children born after a certain date on such children attaining the age of one year, and the offer was accepted by the council. A conference has been held between the sanitary committee of the corporation and the Ladies' Health Society and it was decided to appoint another health visitor in order that the work might be properly carried out. The visitors are to report to, and to be under the control of, the medical officer of health, Dr. J. W. Talent, and he is to be required to attend the meetings of the Health Society. It is probable that these doles, coupled with the increase of sanitary effort on the part of the local authorities and supplemented by the self-denying help given by societies of benevolent ladies, will lead to the spread of knowledge among the mothers and, let us hope, to an increased sense of parental responsibility. It is, however, an uncomfortable reflection that a dole of £1 should in some cases be required to call forth the sense of responsibility and the affection which ought to be a natural instinct with human mothers.

The dinner will be held in the dining hall of the Students' Club at 7 P.M., with Mr. Cosmo Bonsor, treasurer of the hospital, in the chair. At the meeting following the dinner Sir Richard Douglas Powell, Bart., K.C.V.O., will deliver an address on the "Just Procedure of Medicine." Dr. J. F. Goodhart will preside at the meeting.

King's College Hospital.—The winter session will be opened on Oct. 1st, when Professor A. Macalister, LL.D., F.R.S., will distribute the prizes and deliver an address. The annual old students' dinner will be held on the same day, at 7 P.M., at the Waldorf Hotel, Aldwych, Professor M. M. McHardy presiding. Tickets, one guinea each, may be obtained from Dr. StClair Thomson, 28, Queen Anne-street, London, W.

London Hospital.—The session will be opened on Oct. 1st. The old students' dinner will be held on Oct. 1st at the Savoy Restaurant, at 7.30 P.M. Dr. A. J. Rice Oxley will occupy the chair.

St. Mary's Hospital.—The session will commence on Oct. 1st, when Sir John F. H. Broadbent, Bart., will deliver the introductory address at 3.30 P.M. The annual dinner of past and present students will be held in the Whitehall Rooms of the Hotel Métropole on Oct. 2nd, at 7 P.M., with Dr. A. P. Luff in the chair.

Middlesex Hospital.—The session will open on Oct. 1st at 3 P.M., when Dr. A. M. Kellas, Ph.D., will give an introductory address, after which the prizes gained during the previous year will be distributed by Mr. Rudyard Kipling. The annual dinner of the past and present students and their friends will take place at the Trocadéro on the same evening at 7 o'clock precisely, Dr. A. F. Voelcker being in the chair.

St. Thomas's Hospital.—The session will open on Oct. 2nd with the old students' dinner, which will take place at the Savoy Hotel, Strand, W.C., at 7.30 P.M. Mr. Thomas Wakley will preside.

University College Hospital.—The session will open on Oct. 2nd, when the medals and prizes will be distributed in the library of the hospital at 3 P.M., and Sir Edward Fry will deliver an introductory address. The annual old students' dinner will be held on the same day in the library of the school, at 7.30 P.M. Dr. A. H. Carter of Birmingham will preside.

Westminster Hospital.—The session will begin on Oct. 1st and the annual dinner will take place on Oct. 2nd at the Great Central Hotel.

Royal Free Hospital (London School of Medicine for Women).—The session will open on Oct. 1st, when an introductory address will be delivered by Dr. Harrington Sainsbury, physician to the Royal Free Hospital.

THE MEDICAL INSPECTION OF SCHOOL CHILDREN.

THE recent circular of the Board of Education[1] to local authorities has already been dealt with in a leading article, but its provisions require further notice. It was issued under Part III. of the Education Act, 1902, on certain questions arising under recent legislation concerning (*a*) the Functions of the "School Medical Officer"; (*b*) Provision for Medical Inspection of School Children under the Code of 1908; (*c*) the Local Education Authority's Annual Report to the Board of Education on Medical Inspection; and (*d*) Arrangements for Attending to the Health and Physical Condition of School Children. As stated in former circulars, the policy of the Board is to countenance a certain amount of latitude in the administration of the Act providing for the medical inspection of school children until such time as its difficulties and necessary limitations shall have been made clear.

Under the first heading (*a*) the functions of a "school medical officer" are defined. This title has been substituted for the vague expression "medical authority" which was used in the Code of 1907, and implies an official who shall be responsible to the local education authority from which he holds office for supervising and controlling the general work of medical inspection of school children, who shall report on the working and effect of any arrangements made for educating children at an open-air school or school camp, and shall have power to advise the closure of a school or the exclusion of certain children from it on "reasonable grounds." In this last duty the importance of coöperation with the sanitary authority is urged and the Board expects that "the school medical officer will naturally consider the matter from the point of view of education as well as from that of sanitation, and, while keeping in close touch with the medical officer of health will be in a position to advise the local education authority on such difficult matters." The section goes on to say that the Board does not expect that all the work detailed above can be carried out by a single officer in a large area, but that in most cases he will be assisted by subordinates. (*b*) As regards the provision by local education authorities of an adequate staff for the medical inspection of their school children, a blank schedule is appended to be filled up and returned to the Board by each authority stating the estimated number of children for whose inspection provision is to be made; the arrangements made for such inspection; the working instructions given to the staff engaged thereon, and the scope of the work contemplated. The schedule further requires the following information concerning the medical officers and nurses thus engaged:—Name; professional qualification; salary; date of commencement of duties; extent to which these occupy the officer's time (e.g., whole time, one-half, one-third); the nature of duties, distinguishing inspection from treatment; and general remarks. The Board will consider the information returned on these schedules for each area on its own merits with due regard to local circumstances and does not expect uniformity of procedure so long as it is satisfied that the inspection is adequate.

Uniformity is not expected (Section (*c*)) regarding the annual reports to the Board to be returned by local education authorities. These are to deal with the whole subject of school hygiene, including the sanitary, lighting, ventilating, and warming arrangements in each school building as well as with the detailed results of the inspection of the children. A page of the circular is devoted to a long syllabus of matters to be dealt with in the report, and under section (*d*), where their applications are rehearsed under the heading "Arrangements for attending to the health and physical condition of school children," the manifold duties of the school medical officers are described as forming a "formidable catalogue." The circular proceeds to express this opinion: "The mere fact that the services of a specially skilled officer and staff are devoted by the local education authority to the oversight of all matters affecting the health of the children in their public elementary schools gives to the whole question of school hygiene a dignity and importance which cannot but produce a considerable effect on the minds of teachers, parents, and children alike. From this point of view the school medical officer should be not merely a functionary charged with specific duties, but a pervading influence making, in the long run, for better hygienic conditions in the school and at home." The remaining sections under heading (*d*) deal with the exercise of powers under special Acts relating to school children, the methods of coöperation with the sanitary authority, advice or direction to parents, the school nurse and her functions, the provision of spectacles in cases where the parents or some voluntary association are quite unable to procure them; and contributions to hospitals, infirmaries, dispensaries, and "Children's Care Associations" for the treatment of children on terms of adequate advantage, a section which permits the inclusion among conditions of contribution of a reasonable remuneration to the medical men working for such institutions.

The last section deals with school clinics and authorises their establishment at some place more convenient than the school premises for the more thorough *examination* of cases such as ophthalmic cases, where special appliances are required. The Board forbids the use of such clinics for the regular inspection of all the children of any school. The paragraph relating to the *treatment* of children by this means, which brings the circular to a close, is sufficiently important to be quoted in full: "The establishment of School Clinics for purposes of *treatment* of defects revealed by inspection gives rise on the other hand to questions of considerable difficulty, and, before sanctioning the establishment of a School Clinic as an 'arrangement' under Section 13 (1)(*b*) of the Act, the Board will require to be furnished with detailed information as to the methods and

---

[1] No. 596, dated August 17th, 1908, supplementary to Circulars 576 and 582.

and Mr. John Findlay, farmer, Baillieston, dealt with the dairy farmers' interest in the subject. At the close of the discussion a resolution was passed to the effect that the association desired respectfully to bring to the notice of the Secretary for Scotland the urgent necessity for the introduction of a measure dealing with the question of milk-supplies and dairies. Another important discussion, introduced by Dr. T. F. S. Caverhill, medical officer of Haddingtonshire, dealt with the problem of how to isolate and treat cases of pulmonary phthisis so as to limit its spread, and how to do this in the most economical manner. Dr. J. C. McVail, medical officer of Stirlingshire, also gave an instructive lecture on Some Episodes in the History of Preventive Medicine.

Ventilation of Schoolrooms.

It is a curious fact that there are Board of Trade regulations anent the ventilation of factories and workshops, and yet there are no definite regulations, beyond fixing the number of cubic feet per scholar in a room, about ventilation of schoolrooms. The only way in which a check can be administered where the air is bad is by an adverse report from the official inspector, who, of course, cannot know all that is wrong, as he visits a school only about twice a year. Glasgow school board has now turned its attention seriously to the question of ventilation and the older schools are being thoroughly tested and altered, if necessary, on the lines of the Board of Trade's regulations for factories and workshops. A test-sheet is filled up for every schoolroom giving information regarding air-tests, temperature, &c. On these details are based the arrangements for any alterations necessary.

Nairn Town and County Hospital: Handsome Donation.

The annual general meeting of the supporters of the Nairn Town and County Hospital was held on Sept. 3rd when the chairman intimated the receipt by the directors of £500 from an anonymous donor. The donor wished it stated that he had specially in his mind the desirability of increasing the endowment fund of the hospital, and while the income of the investment now made would be at the disposal of the governing body for the general purposes of the hospital, he wished it to be understood that the capital would be held unbroken as a perpetual addition to the endowment fund, and that it would be agreeable to the donor if a minute was passed to the effect that the gift was accepted under that condition. On the motion of the chairman it was unanimously resolved to accept the gift on the condition laid down by the donor and to record the gratitude of the directors and subscribers for the very handsome gift.

Beaufort Castle Bazaar.

The two days' bazaar which was held at Beaufort in the end of last month in aid of the funds for the endowment of the Inverness-shire Sanatorium for Phthisis proved a great success, the total amount realised being close on £4000. The Hon. Margaret Fraser, who promoted the bazaar, received a donation from the Prince of Wales.

Sept. 15th.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

The British Association.

THE British Association has left behind it in Dublin pleasant impressions and recollections of its visit. The inherited *mens medica* of the President was very patent to all medical members of the audience who listened to the opening address and who applauded the reference in his last speech to Irish genius "in their own noble profession, to Graves and Stokes, men who by the brilliancy of their intellectual activity and their innate genius had carved out for themselves an imperishable reputation, and to-day their memories were as warm and as green in the bosom of the nation as at any time in their history—loved, cherished, and respected over the wide world." It is interesting to note that the literary, scientific, and professional distinction of these great physicians still marks the staff of their hospital, the Meath Hospital, for Sir John William Moore and Sir Lambert Hepenstal Ormsby were both contributors to the proceedings of the Association, the former reading an enlightening paper on the ever present subject of our troublesome Irish climate, while the latter in a luminous and happily phrased speech threw a passing light on some abstruse questions of psychology.

The Deportation of Lunatics.

The medical superintendent of the Richmond District Asylum, Mr. John O'Conor Donelan, has stated that among the patients recently admitted were three who had been deported from Scotland under the Poor-law (Scotland) Act, 1898, Section 6. Of these cases one had been no less than 14 years in Scotland prior to being returned here. He wished to draw the special attention of the board to this case as an instance of the hardship to the ratepayers of that district in having patients such as these sent back, while they in Ireland were obliged to retain all patients committed regardless of their nationality. The chairman said the report referred to a most scandalous state of things, and that an effort should be made to have it remedied in the Bill which is to be brought before Parliament in January next. The inquiry of a member elicited the fact that there were many patients at present in the institution who had been received in similar circumstances. The comment might almost be expected that: "England and Scotland get the profit of the Irish labourer's work, and as soon as he becomes mentally or physically incapable he is forthwith deported to a workhouse or a lunatic asylum in Ireland, the country having nothing of the fruits of his toil." The quotation is from a Nationalist source, but medical administrators, whatever their politics, will probably endorse it.

The Forster Green Hospital, Belfast.

This hospital, after the completion of building operations consequent on its enlargement, will be reopened on Oct. 1st for the reception of patients. The number of beds has been increased from 38 to 73 and the medical staff has also been increased. The scope of the out-patient department is also to be enlarged, a medical officer and nurse having been appointed whose duties it will be to keep in touch with the patients after they have been discharged from the hospital and to render them such advice and assistance as may be necessary to insure that the benefits derived from the course of sanatorium treatment may not be lost.

Cold Baths for Tramps.

At the weekly meeting of the Ballymoney board of guardians held on Sept. 10th a letter was read from the Local Government Board with reference to the use of the cold-jet water bath in the probationary ward, which was successfully adopted to deter tramps from applying for admission. It appears that since the introduction of this sanitary appliance the number of tramps coming to the Ballymoney workhouse has fallen from 80 per week to 10. The Local Government Board point out that tepid or warm water should be used for the proper cleansing of persons admitted to the workhouse but that before a cold bath was given to any person in the casual or probationary ward of the workhouse a certificate in writing that the recipient was a suitable case for such treatment should be obtained from the medical officer of the workhouse. It would be the duty of the master to obtain this certificate in every case. A guardian said this would mean an increase of the medical officer's salary, but that he would rather give him £30 per year more than allow the tramps the use of the workhouse. It was decided to call a special meeting of the guardians to discuss the matter.

The Babies' Club, Belfast.

At an inquest held in Belfast on Sept. 9th in reference to the death of an infant, aged five months, from convulsions, it appeared that the child, who had been very delicate, had been kept alive by the gift of a pint of good milk every day from the Ballymacarrett branch of the Babies' Club since July. The coroner referred to this practical form of charity and said that the Babies' Club had shown them how much could be done to save life amongst infants. There were 71 children on the books of this branch and this was the first death. The jury in their verdict added a rider expressive of their high appreciation of the service rendered to the community by the institution known as the Babies' Club. It may be added that the various babies' clubs in Belfast are being worked voluntarily by the infantile committee of the Belfast branch of the Women's National Health Association of Ireland.

history of persons who were known habitually to have consumed this tuberculous milk. There is only one dairy to every 500 persons in Newcastle and consequently Dr. Armstrong infers that most of the milk supplying the population comes from outside the city limits, where there is practically no veterinary inspection of the cattle. It is instructive with reference to this question of tuberculosis to learn that the number of carcasses condemned for this disease was greater during the last nine months of 1907 than for any similar period previously, and that the local butchers' cattle insurance society paid to its members as compensation during 1907 the sum of £438. Dr. Armstrong thinks that a large part of compensation for tuberculous cattle should be paid for out of the public purse. Much boneless meat from America reaches Newcastle and also, of course, many other large towns. Such meat defies inspection and it is not improbable, seeing that the glands and fat are removed, that some of it may be derived from tuberculous carcasses. In Dr. Armstrong's view only whole carcasses, together with their viscera, should be allowed to be imported and everything should be subjected to inspection on arrival. It may be mentioned that in Newcastle the fat of carcasses condemned for tuberculosis has now to be thoroughly sterilised and is used in the manufacture of soap.

County Borough of Salford.—Mr. C. H. Tattersall, who is medical officer of health of this town of 236,670 inhabitants, reports that in 1901 he took into consideration the cost of dealing with pulmonary tuberculosis by the isolation of advanced cases and the treatment of early cases in a sanatorium together with the usual procedure as regards inspection and disinfection. The cost was estimated at £20,000 per annum and the sanitary committee did not feel justified in advising the council to incur such a large expenditure. The subject has again been considered by the committee but on a less comprehensive scale. It has been proposed *inter alia* to convert one of the empty large houses in the borough for the accommodation of eight patients and it is thought that this might be done for £1000 per annum. This sum, together with the expense of bacteriological work, notification fees, medical inspection, salary and provision for disinfection, would, it is estimated, bring the total annual expenditure up to £1550. Voluntary notification has already been introduced and blue and red cards are used for the purpose; the blue card indicating that the sanitary authority is not to interfere, the red cards that the visits of the inspectors are desired, but in no case is this visiting to be allowed to interfere with the opportunity for the patient to earn a livelihood so long as proper precautions are carried out. From July 14th to the end of the year 356 notifications were received, 143 cases to be visited, 213 not to be visited. Although the proposal to form a small hospital has not yet been acted upon the council has retained five beds at the Crossley Sanatorium at a cost of £260 per year. This is a good move as it will educate the council as to the value of these institutions.

County Borough of Huddersfield.—Dr. S. G. Moore, in discussing the behaviour of pulmonary tuberculosis in Huddersfield, gives a chart which, he thinks, demonstrates that the decline in the death-rate from this disease which had taken place up to recent years has now ceased and he concludes that if this arrest persists the only admissible inference is that the general sanitation of the borough is unsatisfactory. We gather that there is a disposition to allow of the erection of back-to-back houses in Huddersfield, a fact which Dr. Moore deplores, and he points out that such houses cannot have as much ventilation and light as through houses. The importance of securing plenty of direct sunlight and through ventilation as an aid to the destruction of the tubercle bacillus is obvious, as shown by numerous bacteriological experiments. Dr. Moore thinks that if every human case of tuberculosis were so dealt with as to render the escape of living tubercle bacilli impracticable there would be no guarantee that the disease itself would be arrested, and the same statement would, he says, hold true were all bovine and other domestic animal tuberculosis prevented. We have, in his view, no proof that the germs of tuberculosis do not normally exist outside of living organisms and that the bacillus may not persist among vegetable surroundings. In his opinion the soundest line of attack is to render the human "soil" unsuitable for the growth of the bacillus.

County Borough of Sunderland.—Dr. H. Renney furnishes in his current annual report some figures relative to the after-history of the cases of pulmonary tuberculosis sent by the corporation to the Stanhope sanatorium. Since June, 1901, 63 persons have been discharged from the institution; of these 35 are dead, 15 well, 6 fairly well, and 7 cannot be traced. Of those who died the average duration of life after discharge from the sanatorium was about two years. There will be considerable differences of opinion as to these figures: 15 well out of 63 treated. But it is difficult to discuss the figures as they are here presented. How many of the 15 who are well have been recently discharged? The fact is this method of presenting the after-results is not satisfactory. What the unprejudiced observer wishes to know is how many of the cases discharged in any given year are alive some four to five years afterwards and to demonstrate this the figures must be kept in the German fashion—i.e., those for each year kept quite separate throughout the successive years of observation. If Dr. Renney will adopt this practice he will be making a useful contribution to our knowledge as regards the after-results of sanatorium treatment.

County Borough of Grimsby.—Dr. W. B. Simpson draws attention to the increasing proportion of the total deaths which takes place in public institutions. The statistics are only available since 1896, when the proportion of deaths in public institutions to total deaths was 3·55 per cent., the percentage in 1906 being 10·45 and in 1907 10·60. It appears, however, that in 1896 the percentage of persons dying in public institutions was an exceptionally low one, as in 1897 it had increased to 6·32 per cent. Nevertheless, the actual increase has been very marked. Dr. Simpson attributes this increase to the growing popularity of public institutions rather than to poverty and in this he is probably correct. As regards the spread of tuberculosis by the milk of tuberculous cows, he furnishes a good instance of the manner in which apparently healthy cows may be spreading the disease by their milk. On examining the carcass of a cow recently killed he found nearly every internal organ studded with miliary tuberculosis and yet the animal had until a short time before death been supplying milk to Grimsby. There was no actual disease of the udder, but, as is now known, the milk may nevertheless contain tubercle bacilli, or if not the milk the excretions which may foul the udder. Dr. Simpson thinks that if only sterilised milk was used for human consumption there would be a very appreciable diminution of tuberculous disease in childhood.

Metropolitan Borough of Hampstead.—The vital statistics of this borough are always of interest owing to the fact that it is inhabited, for the most part, by a well-to-do class where the social conditions conduce to a low marriage-rate, birth-rate, infantile mortality-rate, and death-rate; and to some extent the figures show how intimately health is bound up with good social conditions. Taking the rates in the order mentioned above we find that the marriage-rate for 1907 was 14·2 per 1000 as against a rate for the previous ten years of 13·9 per 1000, the greatest number of marriages having taken place in the third quarter of the year. The birth-rate for 1907 (14·7 per 1000) shows a considerable decrease on the rate for previous years, an interesting circumstance in view of the increased marriage-rate. The birth-rate for London as a whole was 25·6. In Hampstead the greatest number of births was in the second quarter of the year, a fact which gives rise to interesting reflections. The death-rate was only 9·0 per 1000—the lowest on record for Hampstead. With reference to infantile mortality the remarkably low figure of 73 per 1000 births was registered, as against a rate for the whole of London of 116 and for the 76 great towns of 127 per 1000 births. This low infantile mortality Dr. G. F. McCleary attributes mainly to favourable weather conditions. But it has to be mentioned that important steps are taken by way of directly influencing this drain upon our supply of babies, there having been appointed a lady inspector to visit the children whose births are notified under the Notification of Births Act, and there being also a body of health visitors who carry on work in the same direction. The council has also obtained by-laws providing for the paving of back yards.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN 76 of the largest English towns 8336 births and 4433 deaths were registered during the week ending Sept. 12th. The annual rate of mortality in these towns, which had "dog-days." This year the admissions to the "Istituti Antirabbici," where the Pasteur treatment is practised, have been markedly in excess of those of previous years—Milan alone, for the week ending August 1st, having had as many as 40 cases subjected to the cure; in other words, nearly six a day! Farther afield, at Tagliuno, in the province of Bergamo, a hydrophobic dog bit another which, on the development of the malady, succeeded in biting as many as 15 little village children in a few hours. It is strenuously denied by some pathologists that the human subject, affected by hydrophobia, has the "biting impulse" strong upon him. Yet from such a quarter bites have been received; indeed, quite lately in the province of Brescia Dr. Filingardi was bitten by a hydrophobic girl of 15 and hastened to undergo the treatment at the Milanese Institute, from which he came out "cured," as also did Dr. Giuseppe Merlo who had been bitten in the province of Pavia. Rabies is the most communicable of maladies and no Italian physician believes in its developing "spontaneously" in the dog—by the want of water or by privation of sexual coitus, for instance. There can be no case of "infezione rabbica" without an antecedent "lesione infettante" (infecting lesion), such as the bite of another "animale rabbioso" or the contact of a wound or abraded surface with the virus in question. To ask for a "primary case" of rabies seems as absurd as to ask for a primary case of small-pox or measles! As to the virus itself, Negri, in 1903, after a study of its specific agent or special micro-organism, found this in the family of the protozoa. The poison, conveyed in the saliva of the biting animal and through the victim's central nervous system, settles (according to the same pathologist) in the "bulbus rachideus" and ultimately explodes in symptoms having a family resemblance to tetanus. The notion that a hydrophobic animal shows at once as a first sign of its malady a repugnance to water is no longer tenable, but there is something pathognomonic in its demeanour and behaviour which ought, in the case of the domestic dog in particular, to put its owner on his guard. The first days of its illness are, indeed, the most dangerous, for seeing it dejected and suffering its friends are prone to fondle and caress it, and in return to get a bite or even a lick of its tongue over a scratch on the face or finger and so contract the disease. Perroncito of Turin remarks that dogs affected with "rabbia muta"—that is, presenting no sign of "rabbia furiosa"—can impart the poison to the human subject, and cites the case of a carabineer who died from hydrophobia from the dog's licking a wound on his hand. The same expert confirms the finding of Viana that the virus of rabies may be transmitted by a particular insect—a finding arrived at in the case of a dog, and rendered, he thinks, the more certain if, as Negri, Volpino, and Bertarelli maintain, the determinant of the virus is a protozoon, the very minute spores of which may well be transported by an insect. It is not to be supposed that every bite of a hydrophobic animal must necessarily produce hydrophobia. The saliva may no longer contain, after a series of bites, the fatal micro-organism. Of the 15 village children bitten at Tagliuno, perhaps not more than three were actually infected with the virus; but all were sent for treatment to the Pasteur Institute and all came out certified as "cured." This is a source of fallacy in "antirabic" statistics which has often been pointed out by Italian physicians. Nevertheless, the person bitten, old or young, by a hydrophobic animal cannot, if only for precaution, repair too soon to the Pasteur Institute. A treatment which, in Italy alone, has reduced the mortality from 80 per cent. to not more than 3 or even 2 per cent. has a record in its favour much too sound to justify the neglect of it in cases which are even hypothetical only.

The "Feste Torricelliane."

Those of the profession who can take their holiday in October and on the Italian side of the "Watershed" might do worse than spend a few days of it in Florence at the sittings of the Second Meeting of the Italian Association for the Promotion of Science and immediately thereafter accompany the members to Faenza where, on the 24th and 25th of the month, the third centenary of the birth of the inventor of the barometer and founder of the science of hydraulics will be celebrated with special honour. A programme of the proceedings lies before me in which every precaution has been taken to minimise the chances of disappointment or failure seemingly inseparable from celebrations so wide in their reference and so complex in their details. Evangelista Torricelli, indeed, appeals to so many interests, mathematical, physical, hygienic, and even medical, that an "Esposizione" of his "armamentarium scientificum" has had to be brought together, classified, and put conveniently in evidence, to illustrate or supplement the exposition of his life-work which will tax the resources of the orators intrusted with that duty. Trained, while yet the "dew of his youth" was upon him, by the Jesuits of Faenza, many of them masters in the higher literature and in the purer of the sciences, he next came under the spell of Galileo, whose treatise "De Motu" he read to such purpose that he extended its principles to special agents, and in his tractate on the parabolic motion of projectiles he won the esteem and affection of the teacher and so impressed the contemporary world with his genius as to evoke the exclamation: "En revirescit Galilaeus alter." Ferdinand II. dei Medici on Galileo's death made the brilliant young Faventine professor of mathematics in Florence where his grandest achievements were henceforth to see the light. Martini, in his monograph on Torricelli, written expressly for the commemoration, has set these forth in luminous order, dwelling on his "perfezionamento" of the field-glass, his "microscopio rudimentale" made of pellucid "perline di vetro" (tiny pearls of glass), by means of which, primitive as it was, he studied crystallised bodies and laid the foundations of crystallography. In hydraulics he is, *consensu omnium*, the pioneer, the practical result of his operations in those days being the reclamation to fertility of the Val di Chiana (Valley of the Clanis). The barometer, the hygrometer, the aerometer—all these he initiated for posterity to use and to carry to perfection; while in meteorology his theory of the wind, first given to the world before an audience of the Accademia della Crusca, was adopted and developed by Benjamin Franklin. His quadrature of the cycloid, worked out on the lines laid down by Roberval, his quadrature of the parabola, and his essays on the properties of the spiral curve and on centres of gravity, give him rank among the "Dii Majorum Gentium" of mathematics. Martini claims for him an anticipation of the clinical thermometer, effected at the instance of the Grand Duke Ferdinand and utilised to determine fever temperatures in the human subject. All these contributions to science and to the welfare of humanity will be in evidence at the "Esposizione" after previous exposition by orators selected *ad hoc*, and cannot but attract to the commemoration many others besides the compatriots who are so justifiably proud of the man and of his work.

Death of Professor Paolo Emilio Cappello.

This able and accomplished Roman surgeon died on Sept. 2nd after 48 hours of acute suffering from diphtheritic throat, the disease having been contracted when on clinical duty. Professor Cappello was director of the great Hospital of the Consolazione and of the "Ospedale del Bambin Gesù." A brilliant and singularly successful operator, he was called in consultation far beyond the immediate scene of his practice, and leaves many friends, professional and lay, to mourn a loss as heavy as it was unexpected and premature.

Sept. 5th.

VIENNA.

(FROM OUR OWN CORRESPONDENT.)

An Accident Hospital Ward.

SINCE the death of Professor von Mosetig just over a year ago the 100 beds which were under his charge at the hospital have been vacant, as it could not be decided what to do with them. The suggestion that the ward should be converted into an accident hospital, a suggestion supported by the clinical teachers, has been fought by "red tape" with success up to now, but as the affair stands at present all points to the fact that on Oct. 1st the 100 beds will actually become a source of very useful instruction for the students of surgery. The Ministry of Education has arranged with the chiefs of the two surgical clinics (Professor von Eiselsberg and Professor Hochenegg) for the teaching of the surgery of accidents, to be given in combination with the military medical staff, which will also send its accident cases into this ward, whilst every officer of the medical corps will have to

ANALYSIS OF SICKNESS AND MORTALITY STATISTICS IN LONDON DURING AUGUST, 1908.

(Specially compiled for THE LANCET.*)*

CITIES AND BOROUGHS.	Estimated population in the middle of 1908.	NOTIFIED CASES OF INFECTIOUS DISEASE.											DEATHS FROM PRINCIPAL INFECTIOUS DISEASES.											Deaths from all causes.	Death-rate per 1000 living.	Deaths of infants under one year to 1000 births.

* Including membranous croup.

treatment of disease, lupus, &c., with the Finsen light and ultra-violet rays, and had workshops attached for major repairs and renewals for x ray equipment generally. In 1905 sanction was accorded by the Government of India to the provision of 15 complete sets of portable x ray equipment, one complete set of each being located at the headquarter stations of each of the ten divisions of the army (including Burma), and five spare sets were allotted to the headquarters x ray institute, Dehra Dun, to meet emergencies, to replace damaged sets, and to meet additional requirements of divisions and needs of independent brigades. The divisional sets are now in charge of specially qualified medical officers of the army (Royal Army Medical Corps or Indian Medical Service), each of whom receives an extra pay allowance (Rs. 60 = £4 per mensem). These officers are assisted by a medical subordinate in subcharge of the outfit who draws Rs. 30 = £2, or Rs. 15 = £1, per mensem staff pay, according to their grade status, assistant surgeon or hospital assistant, as the case may be. These subordinates are required to hold specialist's certificates awarded after a theoretical and practical course of instructions at the x ray institute, Dehra Dun. The divisional x ray section staff and portable equipment would proceed on active service with the division to which it belonged in the event of mobilisation. As regards war requirements it was also proposed that in addition to the x ray specialist with each general hospital, irrespective of size, there should be one specialist officer for each hospital ship and also one for each x ray section (its officer commanding), instead of one per field hospital as was originally intended. The outfit of each x ray section is packed for travelling purposes in rattan cane panniers covered with waterproof canvas suitable for mule transport. Owing to its fragility and costliness these panniers when employed on field service are carried by specially steady mules each with *one* muleteer. These mules (unlike other medical transport in the army) remain entirely under the control of the officer commanding the field x ray section. The divisional x ray equipment has now been in full working order at the headquarter station hospital of each of the ten divisional areas for some time and has proved an invaluable boon. At Peshawar Station Hospital it has been freely used during the recent frontier expeditions and has done very valuable work connected with such gunshot injuries as occurred amongst both British and native troops of the field force employed.

Medical Registration.

In emphasising the resolution upon the need for a Medical Registration Act in India passed at the last meeting of the Medical Section of the Asiatic Society the Indian medical press remarks upon the supineness of the Indian public in regard to this matter. Yet it is a matter of the greatest importance, as affecting both public and private interests. The general public, however, can hardly be censured for indifference, for it is only recently that any serious or united action has been taken by the profession, the point which then attracted attention being the continued multiplication of self-constituted bodies granting diplomas and licences to practise medicine. These diplomas being colourable imitations of those bestowed by English and Indian Universities had become a serious danger, not only to the profession but also to the public, who have no means of gauging the value of the imposing parchments in the possession of the pupils of these so-called medical schools. There are stated to be no fewer than five such institutions in Calcutta itself. With one exception none of these have adequate hospital or laboratory accommodation and there is no system of outside inspection. Each school grants its own diplomas and men are turned out without either the practical or the clinical experience which the public have a right to demand from those who profess to be fully qualified practitioners according to European standards. Some organising Act such as is now proposed would be a lasting benefit both to the profession and the public, and it is probable that the present agitation will speedily lead to a definite result.

Proposed Waterworks at Puri.

The Bengal Government has recently accorded administrative approval to a detailed scheme for the installation of waterworks at Puri. The scheme is estimated to cost Rs. 3,00,000 in round figures, and towards this the local government has made a grant of Rs. 1,00,000 from provincial revenues. It is understood that the municipality will take a loan of Rs. 50,000 and that another Rs. 25,000 will be contributed from the Lodging House Fund. There will still be a large balance to provide and it is hoped that Indian gentlemen will come forward with subscriptions in aid of the project, more especially in consideration of the reverent regard which every Hindu has for the place as the site of the great Jagannath pilgrimage. Numerous outbreaks of disease at this place, due to a foul water-supply, will be recalled to memory, and many a pious Hindu will, it may be expected, be only too glad to be allowed to assist in establishing a pure water-supply.

Cholera in Madras.

Madras is suffering from a severe outbreak of cholera. On August 3rd there were 22 attacks and 13 deaths; on the 4th there were 20 attacks and 19 deaths.

August 20th.

Obituary.

ROBERT TWENTYMAN LIGHTFOOT, L.R.C.S. EDIN., L.S.A.

Mr. Robert Lightfoot, the well-known and veteran surgeon of Newcastle, became a Licentiate of the Society of Apothecaries of London in the year of Queen Victoria's accession to the throne, having been already entitled to practise four years before that date upon his Scottish diploma. He was born in Waterloo year, and although when he died at Brighton on August 27th last he had reached the great age of 93 he had been in practice in Newcastle until three years ago. He was a native of Carlisle and was educated at Edinburgh, Vienna, Berlin, and Paris. His life snaps a link with a very grim period in the history of medical education, to wit, that of the Burke and Hare murders in Edinburgh. For Mr. Lightfoot was a pupil of John Knox who gained such a pitiable notoriety by buying the bodies of the murderers' victims. Mr. Lightfoot always declared that his famous teacher was ignorant of the source of these "subjects" for dissection. The deceased gentleman was a pupil of whose abilities Knox used to speak very highly and he made him a demonstrator in his school. Mr. Lightfoot started in general practice in Newcastle 70 years ago, and for 67 of them he remained as a practitioner in that town, where he enjoyed widespread popularity and respect, for he was a skilful surgeon and a conscientious medical attendant. He was, moreover, a man of general culture and of wide reading. He was formerly surgeon to the old Asylum for the Blind, now the Victoria School for the Blind. During the last two years he had been in failing health and was resident at Hove. He is survived by his widow who was a daughter of the late Alderman Thomas Bell, and by a son and two daughters. The funeral took place at Newcastle on August 31st, the first portion of the burial service being held in the cathedral; it was attended by the Lord Mayor of Newcastle and the town clerk of the city, representing the city officials; Sir George Hare Philipson, Professor F. Page, and Professor George Murray, representing the medical profession; and a number of personal and professional friends and patients.

We have received from Sir George Hare Philipson the following additional tribute to Dr. Lightfoot's memory:—

"After qualifying as a surgeon, Lightfoot spent some time at the continental schools of medicine at Paris, Berlin, and Vienna. He became familiar with modern languages and throughout his life interested himself with German medical literature. When a student at Edinburgh he was on intimate terms with Liston and was associated with Dr. Knox, the professor of anatomy, in the position of demonstrator. In Mr. Lightfoot has passed away the last man who had a living connexion with those who figure in the history of the great crime that brought about a change of the law that forbade the unclaimed dead to be carried to the dissecting-room. He was an able anatomist and in Lonsdale's 'Life of Dr. Knox' it is stated that the latter used words to this effect: 'There is nothing in the way of anatomical dissection that eyes can see which Lightfoot cannot see, nothing to be done which Lightfoot cannot do.' Mr. Lightfoot soon acquired a large and high-class practice. He was an able and successful operator and gained a reputation as from the 4th Volunteer Battalion, The Queen's Own (Royal West Kent Regiment), to be Captain, with precedence as in the Volunteer Force (dated April 1st, 1908). Lieutenant James Stratton Warrack, from the Eastern Command, Woolwich Companies, Royal Army Medical Corps (Volunteers), to be Lieutenant, with precedence as in the Volunteer Force (dated April 1st, 1908).

3rd Home Counties Field Ambulance: The undermentioned officers, from the East Surrey Bearer Company, Royal Army Medical Corps (Volunteers), are appointed to the ambulance, with rank and precedence as in the Volunteer Force (dated April 1st, 1908): Captain George Alfred Edsell and Lieutenant John Alexander Preston.

3rd Lowland Field Ambulance: Major Alexander Macdonald (since deceased), from the 1st Lothian Bearer Company, Royal Army Medical Corps (Volunteers), to be Lieutenant-Colonel (dated April 1st, 1908). Captain Alexander Aitken Ross, from the 1st Lothian Bearer Company, Royal Army Medical Corps (Volunteers), to be Major (dated April 1st, 1908).

The undermentioned officers, from the 1st Edinburgh (City) Royal Garrison Artillery (Volunteers), are appointed to the ambulance, with precedence as in the Volunteer Force (dated April 1st, 1908): Surgeon-Captain Alexander Morrison McIntosh, and Surgeon-Lieutenant James Hunter Harvey Pirie.

The undermentioned officers, from the Queen's Rifle Volunteer Brigade, The Royal Scots (Lothian Regiment), to be Lieutenants, with precedence as in the Volunteer Force (dated April 1st, 1908): Surgeon-Lieutenant John Dixon Comrie, Surgeon-Lieutenant Harry Alfred Leebody, and Surgeon-Lieutenant John William Keay. Surgeon-Lieutenant John D. Comrie to be Captain (dated June 3rd, 1908).

1st North Midland Field Ambulance: Thomas Ashby Barron to be Lieutenant (dated July 10th, 1908).

3rd North Midland Field Ambulance: Charles Henry Bullen to be Lieutenant (dated July 24th, 1908).

2nd West Riding Field Ambulance: Charles William Eames to be Lieutenant (dated July 1st, 1908).

2nd Wessex Field Ambulance: Lieutenant Alfred Bertram Soltau, from the Devon Bearer Company, Royal Army Medical Corps (Volunteers), to be Lieutenant (dated April 1st), to be Captain (dated April 8th), and to be Major (dated June 25th, 1908). Edward Revely Clarke, to be Lieutenant (dated June 25th, 1908). Charles Rowland Crowther, to be Lieutenant (dated June 25th, 1908). George Hope Warren, to be Lieutenant (dated June 25th, 1908). Fielding Charles Whitmore, to be Lieutenant (dated June 25th, 1908). *William Blackwood*, to be Lieutenant (dated June 25th, 1908).

2nd Eastern General Hospital: Major Charles John Jacomb-Hood, from the Sussex and Kent Bearer Company, Royal Army Medical Corps (Volunteers), to be Lieutenant-Colonel (dated April 1st, 1908). Captain James Augustus Rooth, from the Sussex and Kent Bearer Company, Royal Army Medical Corps (Volunteers), to be Captain, with precedence as in the Volunteer Force (dated April 1st, 1908).

The undermentioned to be officers whose services will be available on mobilisation (dated April 27th, 1908):—To be Lieutenant-Colonels: Henry Seymour Branfoot, Thomas Jenner Verrall, Edmund Hobhouse, and Reginald Francis Jowers.

To be Majors: Edward Forster Maynard, Frederick John Paley, Walter Broadbent, William Watson Griffin, Donald George Hall, Arthur Herbert Buck, Charles Frederick Bailey, and Theodore Henry Ionides.

To be Captains: Frank George Bushnell, Walter Andrew Bowring, Richard Whittington, William Herbert Brailey, William Dobree Calvert, Henry Herbert Taylor, Henry Gervis, George Morgan, Charles Henry Benham, Leonard Arthur Parry, Arthur Maurice Colcutt, Robert Sanderson, Joseph Shardlow, Arthur Jaffray Hutchison, Charles Nugent Chadborn, Arthur Geoffrey Bate, Morris Notley John Rigby, Arthur Mantell Daldy, Ryder Percival Nash, and Walter Robert Wood.

1st Scottish General Hospital: The undermentioned to be officers whose services will be available on mobilisation (dated June 27th, 1908):—To be Lieutenant-Colonels: John Gordon, James Mackenzie Booth, James John Young Dalgarno, and John Marnoch.

To be Majors: Robert Gordon McKerron, Henry McIlree Williamson Gray, George Gibb, George *Rose*, Alexander Rudolf Galloway, Charles Howard Usher, William Rattray Pirie, and David Watson Geddie.

To be Captains: John Reid Levack, Henry Peterkin, and James Melville Paterson Crombie.

2nd Scottish General Hospital: Lieutenant-Colonel Frank Wyville Thomson (late Indian Medical Service), to be Lieutenant-Colonel (dated July 21st, 1908).

1st Western General Hospital, Royal Army Medical Corps: Nathan Raw, to be Lieutenant-Colonel (dated July 7th, 1908). Archibald Burns Gemmel to be Major (dated July 7th, 1908).

Sanitary Service: Frederick Mann Williams, late Lieutenant 2nd (Prince of Wales) Volunteer Battalion, The Devonshire Regiment, to be Lieutenant-Colonel (dated July 28th, 1908).

The undermentioned officers, from the Volunteer Force, are appointed to the Corps, with precedence as in the Volunteer Force (dated April 1st, 1908):—To be Lieutenant-Colonels: Supernumerary Surgeon-Lieutenant-Colonel (Honorary Lieutenant-Colonel in the Army) James Duncan, from the 3rd Volunteer Battalion, The Manchester Regiment; Supernumerary Surgeon-Lieutenant-Colonel Frederic Joseph Knowles, from the 2nd Volunteer Battalion, The Prince of Wales's Volunteers (South Lancashire Regiment); Surgeon-Lieutenant-Colonel *Thomas Moore* Dawson, from the 1st Lancashire Royal Garrison Artillery (Volunteers); Surgeon-Lieutenant-Colonel George Hollies, from the 2nd Volunteer Battalion, The King's (Shropshire Light Infantry); Surgeon-Lieutenant-Colonel (Honorary Major in the Army) Andrew Alexander Watson, from the 2nd Volunteer Battalion, The East Lancashire Regiment.

To be Majors: Surgeon-Major Charles Averill, from the 5th Volunteer Battalion, The Cheshire Regiment; Surgeon-Major John Tatham Thompson, from the 3rd Volunteer Battalion, The Welsh Regiment; Surgeon-Major John William Ellis, from the 6th Volunteer Battalion, The King's (Liverpool Regiment); Surgeon-Major Ernest Wykeham Barnes, from the 6th Volunteer Battalion, The King's (Liverpool Regiment); Surgeon-Major Henry Christopher Lamport, from the 5th Lancashire Royal Garrison Artillery (Volunteers); Surgeon-Major James Arthur Rigby, from the 5th Lancashire Royal Garrison Artillery (Volunteers); Surgeon-Major William Fitzwilliam O'Grady, from the 1st Volunteer Battalion, The Manchester Regiment; Surgeon-Major Stephen Nesfield, from the 5th (Ardwick) Volunteer Battalion, The Manchester Regiment; Surgeon-Major Robert Jackson, from the 2nd Lancashire Royal Engineers (Volunteers); Surgeon-Major Thomas Stevenson, from the 2nd Lancashire Royal Garrison Artillery (Volunteers).

To be Captains: Surgeon-Captain John Howard-Jones, from the 4th Volunteer Battalion, The South Wales Borderers; Surgeon-Captain Charles Evan Humphreys, from the 5th Volunteer Battalion, The South Wales *Borderers*; Surgeon-Captain Albert Hilton, from the 3rd Volunteer Battalion, The Manchester Regiment; Surgeon-Captain Henry D'Arnim Blumberg, from the 3rd Volunteer Battalion, The King's (Liverpool Regiment); Surgeon-Captain *Elisha* Hodkinson Monks, from the 2nd Lancashire Royal Engineers (Volunteers); Surgeon-Captain Charles William Crawshaw, from the 2nd Volunteer Battalion, The East Lancashire Regiment; Surgeon-Captain Arthur Price, from the 4th Volunteer Battalion, The King's (Liverpool Regiment); Surgeon-Captain Alan Young Greenwood, from the 3rd Lancashire Royal Garrison Artillery (Volunteers); Surgeon-Captain (Honorary Lieutenant in the Army) Michael Joseph Mahoney, from the 6th Volunteer Battalion, The King's (Liverpool Regiment).

To be Lieutenants: Surgeon-Lieutenant Harry Armitage Robinson, from the 2nd Lancashire Royal Garrison Artillery (Volunteers); Surgeon-Lieutenant Arthur Henry Falkner, from the 2nd Volunteer Battalion The King's Own (Royal Lancaster Regiment); Surgeon-Lieutenant Frederick James Green, from the Duke of Lancaster's Own Imperial Yeomanry; Surgeon-Lieutenant Howard Henry, from the 1st Volunteer Battalion The East Lancashire Regiment; Surgeon-Lieutenant Douglas Catterall Leyland Orton, from the 2nd Volunteer Battalion, The Prince of Wales's Volunteers (South Lancashire Regiment); Surgeon-Lieutenant Samuel English, from the 3rd Lancashire Royal Engineers (Volunteers); Surgeon-Lieutenant Samuel Edward Rigg, from the 1st Cumberland Royal Garrison Artillery (Volunteers); Surgeon-Lieutenant Charles Botterill Baxter, from the 2nd Volunteer Battalion, The King's (Shropshire Light Infantry);

wreath from the Lincoln Medical Society, of which he had long been a member.

JOHN TAYLOR, M.R.C.S. Eng., L.S.A.

By the death of Mr. John Taylor at Earls Colne on Sept. 4th East Anglia loses one of the oldest members of the medical profession in the district. Mr. Taylor was in his ninetieth year, having been born in 1819. His father, Mr. John Polley Taylor, commenced to practise in Earls Colne in 1812. Mr. John Taylor the younger entered as a student at St. George's Hospital and subsequently became a pupil of Mr. Isaac Baker Brown. He qualified M.R.C.S. in 1842, L.S.A. in 1845, and joined his father in practice at Earls Colne, and on the decease of his father succeeded to the entire practice in 1856. He was medical officer and public vaccinator of the third district of the Halstead union for 50 years and also many years medical officer and public vaccinator of the tenth district of the Lexden and Winstree union. For some years he was President of the Colchester Medical Society, of which he was a member for 62 years, and only last month he again had the honour offered him. He was greatly interested in the Essex and Herts Medical Benevolent Society, being a trustee for Essex for many years. He was of a most hospitable and genial nature and was a keen sportsman, being preatly interested in fox hunting and cricket. He took a geen interest in all matters appertaining to his profession knd to the last kept himself as far abreast as possible of advancements in medicine. The funeral took place on Sept. 8th at Earls Colne and the respect in which he was held was shown by the large number of medical men and friends of all classes who attended from the whole country side.

WALTER BROWN, M.B. Aberd., L.R.C.P. Lond., M.R.C.S. Eng.,

PHYSICIAN TO THE GLOUCESTER GENERAL INFIRMARY.

The death occurred on Sept. 12th, at his residence, Carlton House, Gloucester, of Dr. Walter Brown. The deceased gentleman graduated M.B. of the University of Aberdeen in 1879, having taken the qualifications of M.R.C.S. Eng. and L.R.C.P. Lond. in 1874 and 1875 respectively. After holding resident appointments at the Victoria Hospital for Children, Chelsea, and the Royal United Hospital, Bath, Dr. Brown was appointed house surgeon at the Gloucester General Infirmary. On resigning the latter post he commenced practice at Gloucester and was subseqently elected assistant physician, and later physician to the General Infirmary. Dr. Brown was a prominent Freemason, he was extremely popular in Gloucester, and much sympathy is felt there for his widow and young family.

Deaths of Eminent Foreign Medical Men.—The deaths of the following eminent foreign medical men are announced:—Professor J. G. Hjalmar Kinberg of Stockholm, well known both as a medical practitioner and as a zoologist. He was 89 years of age.—Prince Ivan R. Tarkhanoff, who was for many years professor of physiology in the Military Medical Academy, St. Petersburg. Since 1895, when he resigned the chair, he has been actively engaged lecturing as *privat-docent* on biology and physiology and in publishing papers and periodicals dealing with medicine and science in a popular way. Prince Tarkhanoff was born at Tiflis in 1846 and studied medicine in St. Petersburg, Strasburg, and Paris.

Medical News.

Foreign University Intelligence.—*Berlin:* Dr. Ulrich Friedemann has been recognised as *privat-docent* of Bacteriology.—*Bologna:* Dr. Casimiro Doniselli has been recognised as *privat-docent* of Experimental Physiology, and Dr. Arturo Beretta as *privat-docent* of Odontology.—*Chicago (North-Western Medical School):* Dr. William A. Evans, of the Chicago College of Physicians and Surgeons, has been appointed to the Chair of Hygiene; Dr. Prentiss has been appointed Assistant Professor of Anatomy; Dr. W. H. Buhlig, Assistant Professor of Medicine; Dr. R. T. Gilmore, Assistant Professor of Gynæcology; and Dr. Joseph Brennemann, Assistant Professor of Children's Diseases.—*Florence:* Dr. G. Greco, Professor of Surgery, has resigned his chair.—*New Orleans:* Dr. G. Mann has been appointed Professor of Physiology.—*New York (Cornell University):* Dr. S. Simpson of Edinburgh has been appointed to the chair of Physiology.—*Pisa:* Dr. Francesco Niosi has been recognised as *privat-docent* of External Pathology.—*Rio de Janeiro:* Dr. Miguel da Silva Pereira has been promoted to the chair of Internal Pathology.—*Rome:* Dr. Marco Almagià has been recognised as *privat-docent* of General Pathology; Dr. Giambatista Mariotti Bianchi as *privat-docent* of Pathological Anatomy; Dr. Nicola Leota as *privat-docent* of External Pathology; and Dr. Attilio Ascarelli as *privat-docent* of Forensic Medicine.—*Turin:* Dr. Eugenio Delfino has been recognised as *privat-docent* of External Pathology and Dr. Vittorio Marzocchi as *privat-docent* of Parasitology.

St. George's Hospital: a Proposed Hospital Club.—On Oct. 1st next, at 2.30 p.m., a meeting of past and present St. George's Hospital students will be held in the Medical School with the object of promoting a St George's Hospital Club. The club will include the present Amalgamation Club, the Graphic Society, and the Hunterian Society; whilst the *St. George's Hospital Gazette* will become the official organ of the new club and will in future be forwarded to members. The objects of the St. George's Club will be to extend and cement the associations between all St. George's men, past and present, and to keep them informed of news concerning the hospital and school. Dr. T. T. Whipham, consulting physician to the hospital, who will preside at the annual dinner of the Medical School at the Hotel Métropole in the evening, has kindly consented to become the first president of the club. It is hoped that all St. George's men will do their best to be present at the inaugural meeting. Those who may not have received an invitation by post are requested to send their present address to the honorary secretaries of the club, St. George's Hospital, London, S.W. All life members of the Amalgamation Club will become, *ipso facto*, life members of the new club.

Brighton and Sussex Medico-Chirurgical Society.—A meeting of this society was held on Sept. 3rd, Mr. R. F. Jowers, the new President, being in the chair. The President showed a case of Fracture of the Neck of the Humerus in which the lower fragment was pulled upwards and forwards so as to overlap the upper fragment. The fracture was exposed between the deltoid and pectoralis and the bones secured in position by two staples, one on each side of the biceps tendon. The result was excellent Dr. Walter Broadbent showed a man with Aneurysm of the Third Part of the Arch of the Aorta. He had a paralysed left vocal cord, unequal pupils, smaller left pulse, tracheal tugging, pulsation, dulness, and loud second sound in the first and second left spaces, also a harsh systolic murmur loudest over this area and less air entry in the upper lobe of the left lung. He had been under his care for 18 months. Mr. A. J. Martineau showed a man, 50 years of age, with a Perforating Ulcer of the Palate, said to have been started by an injury from a pipe stem. There was no history of syphilis, but improvement had taken place under iodide and inunctions of mercury. He also showed a woman, aged 32 years, who had suffered from Aphonia for several months which appeared to be functional. As she had a goitre the right lobe was removed under chloroform and the voice returned the same evening. The goitre appeared to exert no pressure on the trachea. Mr. G. Morgan showed a large Sarcomatous Gland removed from the groin of a boy aged two years. Dr. C. H. Benham showed an Ovary of the size of a bantam's egg, black from effused blood and gangrene, due to a twisted pedicle, removed for him from a child, aged nine years, by Mr. Jowers. The child had had six attacks of acute pain in the right lower abdomen with vomiting in the last two years, and when seen by Dr. Benham had tenderness at McBurney's point and the blood showed a leucocytosis of 12,500, mainly polynuclear. Dr. Benham also read a paper on the Treatment of a Common Cold. He first dealt with prophylaxis, recommending isolation of the first case in a house; then with treatment of acute colds in the early stages with quinine or salicylates, and of chronic colds with tonics and nasal douches. He went fully into the opsonic and vaccine treatment of will be under the charge of Captain Pinch, to whom all communications should be addressed. It is not intended to keep the exhibition open longer than one month, beginning Oct. 1st. Exhibitors are invited to be responsible for the removal of their drawings, but false-backed frames will be provided for their secure exhibition under glass whilst displayed. The exhibition is open to all members of the profession on presentation of card, but those who desire to consult it more than once or to attend any lectures that may be given are invited to subscribe to the Polyclinic funds the sum of 1 guinea.

I am, Sir, yours faithfully,
JONATHAN HUTCHINSON.
The Polyclinic, Chenies-street, Sept. 14th, 1908.

RUPTURE OF THE LIGAMENTUM PATELLÆ.

To the Editor of THE LANCET.

SIR,—The statement in your annotation under the above heading in THE LANCET of Sept. 12th, p. 825, that rupture of the ligamentum patellæ has seldom been recorded has prompted me to send you the notes of the following case.

A man, aged 29 years, on Nov. 11th, 1902, slipped and fractured his right patella. No operation was performed and he recovered with very fair movement in the knee, being able to carry on his ordinary employment quite well. On August 13th, 1907, he slipped and fractured the same patella again. I saw him with Mr. A. J. D. Riddett and advised operation. This was performed a week later, when it was found that the second fracture was through the middle of the upper fragment, the original fracture being firmly united with fibrous tissue with half an inch interval between the fragments. The edges of the recent fracture were sawn off and then wired firmly together; the fibrous union of the original fracture was not interfered with. The result was quite good and the man returned to his work after three months, which he carried on till August 29th, 1908, when he slipped once more and felt his knee go again.

I again saw him with Mr. Riddett and found a lot of effusion in and round the joint with total inability to lift the leg. We decided to operate again, especially as the patient wished it, saying that his leg had felt much stronger since the last operation. On opening up the old scar we found that the patellar ligament was torn right through just below the attachment to the patella. The second fracture was found to have united with firm bony union. The old silver wire was removed and the ligamentum patellæ fixed firmly to the lower border of the patella with silver wire and some silk sutures. The original fracture was in the same condition as at the previous operation. The wound has now healed and it will be interesting to see what the functional result will be and also whether it will be the quadriceps tendon's turn to go the next time he falls.

I am, Sir, yours faithfully,
F. BOLTON CARTER.
Leicester, Sept. 12th, 1908.

THE VARIATIONS IN THE PHAGOCYTIC POWER OF LEUCOCYTES FROM DIFFERENT INDIVIDUALS AND ITS BEARING UPON THE OPSONIC INDEX.

To the Editor of THE LANCET.

SIR,—Sir A. E. Wright has stated that "we may take the opsonic index of any blood as an index of the patient's power of phagocytic response."[1] According to this one person is less resistent to a staphylococcic infection than another, partly because his blood is deficient in opsonin, certainly not because there is an inherent deficiency in the phagocytic capacity of the leucocytes themselves.

In a paper read by two of us (E. E. G. and W. Y.) before the Pathological Society of Great Britain and Ireland in January, 1908, we stated that the phagocytic power of the leucocytes of one individual may constantly differ from that of another individual. This was tested according to the technique of Wright with an emulsion of staphylococcus albus.

We have recently made further observations upon the blood of two individuals, "A" and "G," estimating the degree of phagocytosis to staphylococcus obtained with (1) "A's" and "G's" serum respectively with the *same* leucocytes—i.e., comparing the opsonising influence of the serum upon phagocytosis; (2) "A's" and "G's" leucocytes respectively with the *same* serum—i.e., comparing the influence of the leucocytes upon phagocytosis; and (3) "A's" serum with "A's" leucocytes and "G's" serum with "G's" leucocytes—i.e., comparing the total phagocytic power of the blood. Three indices were calculated in this way, using "G" as control at intervals of three days for one month. On July 20th, for example, "A's" indices were the following: (1) 1·15 (mean of three separate observations), (2) 0·83 (mean of three separate observations), and (3) 0·98 (mean of two separate observations). Therefore, though "A's" opsonic index was definitely above that of the control the total "power of phagocytic response" was practically equal, because "A's" leucocytes were deficient in inherent phagocytic power. "A's" and "G's" red corpuscles were not agglutinated by any of the sera used; systematic examination of their blood revealed no leucocytosis.

We intend at an early date to publish a detailed account of the observations we have in hand and the conclusions we have arrived at.

We are, Sir, yours faithfully,
ERNEST E. GLYNN, M.A., M.B. Cantab., M.R.C.P. Lond.,
Lecturer in Clinical Pathology and Morbid Anatomy, University of Liverpool; Pathologist to the Liverpool Royal Infirmary;
WARRINGTON YORKE, M.B., Ch.B. Liverp.,
Late Holt Fellow in Physiology, University of Liverpool;
G. L. COX, M.A., M.B. Cantab.,
Holt Fellow in Pathology, University of Liverpool.
August 24th, 1908.

A PERSONAL MATTER.

To the Editor of THE LANCET.

SIR,—My attention has been directed to the recent distribution, for advertising purposes, of a pamphlet bearing my name. The facts are as follows:—

In 1906, when acting as foreign editor of a medical journal, the editor asked me to make an abstract of an article in the *Berliner Medizinische Klinik* by Professor Gumpert. The abstract was published as an article under my name, although I had given no authority therefor; it is the only time my name has appeared in this journal. Copies of my abstract were bought, I believe in good faith, from the journal in which the abstract appeared, the sale being without my consent or knowledge. The heading "A Contribution, &c. By T. P. Beddoes," has led many to conclude that I claim the credit of the original work described, which is entirely due to Professor Gumpert and his collaborators.

Yours faithfully,
T. P. BEDDOES.
Sept. 14th, 1908.

⁂ We should be interested to learn the name of the medical journal.—ED L.

THE PREVENTION OF TUBERCULOSIS (IRELAND) BILL.

To the Editor of THE LANCET.

SIR,—May I say that I believe your attitude with regard to the Compulsory Notification Clauses of the Irish Tuberculosis Bill is entirely wise? Unlike Sir John Byers, I am not a professor of midwifery, but, after all, a medical man who is a member of a sanitary authority is perhaps in closer touch with the prejudices of people who will be affected by the Bill.

Knowing what I do of the Irish people, I believe that the Compulsory Notification Clauses will excite so much suspicion and dread as effectually to undo any good result heretofore obtained from the tuberculosis campaign. People simply will not go to a medical man if they think that by so doing they may be listed as tuberculous. I fully recognise that the anti-tuberculosis movement in Ireland has done much good, but it has a source of weakness in not being largely controlled by those in close touch with the popular party—and thus its mental and nervous diseases in Lower Austria, "am Steinhof," which is reputed to be the largest public establishment of its sort in Europe, to the Mauer-Öhling asylum, and to the Moravian establishments. During the Congress a bust of Krafft-Ebing will be unveiled in the university. The full programme of proceedings will be published shortly. The President of the Congress is Hofrat Professor Dr. Obersteiner, 1, Billrothstrasse, 69, Wien XIX/1, and the general secretary is Professor Dr. Pilcz, Wien XIII/12.

---

Appointments.

Successful applicants for Vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column, are invited to forward to The Lancet *Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week, such information for gratuitous publication.*

Benson, C. T. V., M.R.C.S., L.R C.P. Lond., has been appointed to the Throat Department and to the Children's Surgical Department at St. Thomas's Hospital.

Corbett, C. D. H., B.A. Oxon., M.R.C.S., L.R.C.P. Lond., has been appointed to the Throat Department and to the Children's Medical Department at St. Thomas's Hospital.

Hancock, George Charles, M.R.C.S. Eng., L.R.C.P. Lond., D.P.H. (Eng. Conj.), has been appointed Assistant Inspector of Foods on the Medical Staff of the Local Government Board.

Hodgson, Stanley, M.D., B.S. Lond., M.R.C.S., L.R.C.P. Lond., has been appointed District Medical Officer to the Salford Union and Divisional Police Surgeon to the Salford Police.

Huggins, G. M., M.R.C.S., L.R.C.P. Lond., has been appointed House Surgeon to Block 8 at St. Thomas's Hospital.

Leigh, John Dickinson, M.D. Edin., F.R.C.S. Edin., D.P.H., has been appointed Medical Inspector of Schools by the Durham County Council.

McSheehy, O. W., M.R.C.S., L.R.C.P. Lond., has been appointed to the Skin Department at St. Thomas's Hospital.

Montesole, M. H. E. R., M.R.C.S., L R.C.P. Lond., has been appointed Senior Obstetric House Physician at St. Thomas's Hospital.

Morton, Edwin, M.D. Edin., has been appointed Medical Superintendent and Adviser to the Education Committee of the Oxfordshire County Council.

Neild, F. M., M.B., B.S. Lond., has been appointed Junior Obstetric House Physician at St. Thomas's Hospital.

Pridham, G. H., M.R.C.S., L.R.C.P. Lond., has been appointed to the Children's Medical Department at St. Thomas's Hospital.

Shorland, Walter Edmund, L.R.C.P. Lond., M.R.C.S., has been appointed *pro tem.* Medical Officer and Public Vaccinator for the Llandilo (Carmarthenshire) District by the Llandovery Board of Guardians.

Wheeler, J. N., M.R.C.S., L R.C.P. Lond., has been appointed Ophthalmic House Surgeon at St. Thomas's Hospital.

Vacancies.

For further information regarding each vacancy reference should be made to the advertisement (see Index).

Birkenhead Borough Hospital.—Junior Resident House Surgeon. Salary £80 and notification fees.

Birmingham and Midland Free Hospital for Sick Children.—Resident Medical Officer and Resident Surgical Officer for six months. Salary at rate of £80 per annum each, with board, washing, and attendance.

Birmingham, Queen's Hospital.—House Surgeon for six months. Salary at rate of £50 per annum, with board, lodging, and washing.

Bolton, County Borough of.—Assistant Medical Officer of Health and School Medical Officer. Salary £250 per annum, rising to £300.

Bradford, Poor-law Union Hospital and Workhouse.—Assistant Resident Medical Officer, unmarried. Salary £100, with rations, apartments, and washing.

Brighton, Sussex County Hospital.—House Surgeon, unmarried. Salary £120 per annum, with board, residence, and washing.

Bristol Royal Infirmary.—Resident Casualty Officer for six months. Salary at rate of £50 per annum, with board, lodging, and washing. Also House Surgeon. Salary £130 per annum, with apartments, board, and laundry.

British Lying-in Hospital, Endell-street, W.C.—Resident Medical Officer. Salary at rate of £50 a year, including board, lodging, and washing.

Camberwell House Asylum, 33, Peckham-road, S.E.—Second Assistant Medical Officer, unmarried. Salary £150, rising to £200, with board, apartments, and laundry.

Cancer Hospital, Fulham-road, London, S.W.—Assistant Anæsthetist. Salary 25 guineas per annum.

Chester County Asylum.—Third Assistant Medical Officer, unmarried. Salary £160 per annum, with board, lodging, and washing.

Denbigh, Denbighshire Infirmary.—House Surgeon. Salary £100, with board, residence, and washing.

[illegible] Greenwich.—Two House Physicians and [illegible] six months. Salary £50 per annum, with [illegible] ishing.

Dudley, The Guest Hospital.—Assistant House Surgeon. Salary £60 per annum, with residence, board, and washing.

Evelina Hospital for Sick Children, Southwark Bridge-road, London, S.E.—House Surgeon. Salary at rate of £60 per annum, with board, residence, and washing. Also Clinical Assistants.

Exeter, County Education Office.—Medical Officers for Inspection of Children.

Farningham and Swanley, Kent, Homes for Little Boys.—Medical Officer, unmarried. Salary £100 a year, with board, residence, and laundry.

Gartcosh, Glasgow District Asylum.—Assistant Medical Officer. Salary commencing at £125, with board and lodging.

Gordon Hospital for Fistula, &c., Vauxhall Bridge-road, S.W.—Anæsthetist.

Grimsby and District Hospital.—House Surgeon. Salary £120 per annum, with board, lodging, attendance, and washing.

Hampstead General Hospital.—House Physician and House Surgeon, both for six months. Salary at rate of £70 per annum, with board and residence.

Hereford, Herefordshire General Hospital.—House Surgeon, unmarried. Salary £100 per annum, with board, apartments, and washing.

Hospital for Consumption and Diseases of the Chest, Brompton —Resident House Physicians for six months. Salary £25. Also Resident Medical Officer. Salary £200 per annum, with board and residence. Also Assistant Resident Medical Officer. Salary £100 per annum, with board and residence. Also Clinical Assistants for six months. Salary at rate of £100 per annum.

Huddersfield Infirmary.—Junior House Surgeon. Salary £60 per annum, with board, residence, and washing.

Jersey General Dispensary and Infirmary.—Resident Medical Officer. Salary £120 per annum.

Lancaster, Royal Lancaster Infirmary.—House Surgeon, unmarried. Salary £100 per annum, with residence, board, attendance, and washing.

Leamington, Warneford, Leamington, and South Warwickshire General Hospital.—Two Resident Medical Officers. Salary for Senior £100, and for Junior £65 per annum, with board, washing, and apartments.

Leicester Infirmary.—Assistant House Surgeon; also Assistant House Physician, both for six months. Salaries at rate of £60 per annum, with board, lodging, and washing.

Leysin, Switzerland, English Sanatorium.—Assistant Medical Officer, unmarried. Salary at rate of £72 per annum for first six months, afterwards at £96, with board and lodging.

London Hospital, Whitechapel, E.—Assistant Surgeon.

Mandalay Municipality.—Health Officer. Salary Rs.600 (£40) per mensem.

Mount Vernon Hospital for Consumption and Diseases of the Chest, Hampstead.—Junior Resident Medical Officer. Salary £50 per annum, with board, lodging, &c.

Newcastle-upon-Tyne Education Committee.—Assistant Medical Officer. Salary £250 per annum.

THE EYESIGHT OF CHILDREN ATTENDING ARMY SCHOOLS IN INDIA.

(FROM AN INDIAN CORRESPONDENT.)

THE hygienic condition of army schools in India, particularly with regard to the question of vision, has recently been the subject of an inquiry. Specialists in ophthalmology were sent to the following stations to examine the vision of the children of British soldiers over seven years of age, and to give the parents concerned necessary information regarding the spectacles required where such were considered necessary:—Rawal Pindi, Peshawar, Nowshera, Ambala, Sialkot, Calcutta, Bareilly, Fyzabad, Lucknow, Meerut, Karachi, Mhow, Ahmednagar, Poona, Kirkee, and Bombay. The inspecting officers were also directed to report on the lighting of schools and the structural alterations necessary to improve it, together with the type of desks and seats used, with special reference to their adaptability for proper vision, and other subsidiary factors connected with the vision of school children. The result of these inspections is briefly as follows.

VISION.

This was tested by means of Snellen's test types, every child being required to read with each eye separately D–6 at 20 feet and D–0·6 at 10 inches. Any child who could not read the types was subsequently seen at hospital, where the refraction was ascertained under a mydriatic. The parents were then informed of the nature of the visual defect and advised as to what spectacles to procure. With few exceptions the parents provided the glasses at their own expense. The result of the examinations is shown in the following table:—

—	Actual numbers.	Percentages.
Total number examined	612	—
Number with defective vision	99	16
Hypermetropia	*55	11
Hypermetropic astigmatism	12	
Myopia	7	2
Myopic astigmatism	7	
Mixed astigmatism	7	1
Leucoma	2	—
Aphakia	1	—
Convergent squint...	†18	3
Divergent squint	‡1	
Trachoma	13	—
Nystagmus	1	—
Dislocation of lens	1	—

* Includes 16 cases of squint.
† Hypermetropic, 15; leucoma, 2; aphakia, 1. ‡ Hypermetropic.

Slight cases of hypermetropia with 6/6 vision, in which muscular equilibrium was perfect and which did not require correction by glasses, are not shown amongst those with defective vision. In one case, a child with myopic astigmatism was found to be wearing + 1 spheres. In another class a child was found with 1/60th vision (each eye) due to partial dislocation of the lenses. In several cases it is remarked that children who were considered wanting in intelligence became quite bright and intelligent after the supply of glasses. The percentage of cases of myopia is much the same as is usually found in school children of the age examined. The large majority of children seen were below 12 years of age, whereas myopia attains its greatest frequency between 12 and 18 years.

It will be noticed that 19 cases of squint were found. According to Worth, 75 per cent. of cases of unilateral squint appear before the end of the fourth year, and in 53 per cent. of alternating cases the deviation is seen before the end of the second year. This being so, it appears desirable that the eyes of all children should be examined by a medical officer for early signs of squint and other visual defects before school attendance is commenced.

LIGHTING.

With the exception of the schoolrooms at Karachi and Colaba, the lighting in all cases was found to be defective and in some instances very bad, notably the schools for adults and elder children at Calcutta, Fyzabad, Ahmednagar, Rawal Pindi (cavalry) and Mhow (cavalry), and the infants' school at Meerut. The rooms referred to at Ahmednagar and Mhow are described as very dark and ill-ventilated. In some schools the lighting was so defective that the inspectors found that lamps had to be used on dull mornings. The defective lighting was found to be due chiefly to the fact that most schools were not built as such, but are old barrack-rooms re-appropriated and so constructed that to improve the lighting is a difficult matter. The defects in lighting have been brought to notice and representations made indicating the structural alterations necessary to improve it so as to render the building suitable for school purposes. In the majority of cases this can be done at small expense by enlarging and increasing the number of clerestory windows, reducing the woodwork in windows, and increasing the glass area generally. The necessity for so arranging matters as to insure a larger glass area on the side (left side of the pupils) from which the major portion of the light enters has been pointed out. It has been recommended that sunshades should be removed from all clerestory windows on the north side and that those over other windows should be hinged so that they may be raised during the winter months. Attention has been drawn to the desirability of colour-washing the walls of schools pale green and a recommendation has been made that an order should be issued and embodied in regulations to this effect. Softer light would be obtained and glare from the walls would be prevented. In nearly all schools the walls are at present whitewashed.

DUTIES OF TEACHERS IN CONNEXION WITH EYESIGHT.

In addition to the defective lighting the report states that in many cases the light is not properly directed on to the desks. In some cases children are to be seen sitting facing the glare from windows, while in others they have their backs to the light, or the light comes from the right. This incorrect placing of desks is due in some cases to ignorance on the part of teachers of the fact that the preponderance of light should always come from the "left" of the scholars; in other cases it is due to inability on the part of schoolmasters so to arrange the desks as to obtain the above effect, as a result of narrowness of the rooms, length of desks, or difficulty in arranging classes and blackboards so that a side light from the left is obtained. Considering this, and the fact that 19 cases of squint were found, of which some had not been sent to hospital for treatment, it would appear that army schoolmasters fail to realise their responsibilities in preventing the deterioration of vision of the children who are constantly under their observation. With a view to rectifying this a short list of instructions detailing "the duties of schoolmasters in connexion with eyesight" has been drawn up.

DESKS AND SEATS.

In all schools (with the exception of five desks at Rawal Pindi and a few at one or two other stations) the desks and seats are very unsuitable for children. Those supplied for elder children are in nearly all cases too high, being intended for men. The result is that children seated at such desks assume faulty positions; the feet hang some distance from the ground or rest in an awkward position on foot-rails, and the weight is supported partly on the left arm and partly on the chest which is pressed against the desk. In all cases the seats are too broad; in very few instances have back-rests been provided, and even when present they slope at too great an angle. The seats are forms and are placed at varying distances from the desks, the result being that to reach the desk the body is bent forward and the head falls towards the desk as the muscles of the neck become tired. The eyes being too near the book accommodation and convergence are strained, the eyeball is compressed by the recti muscles, and myopia or strabismus is liable to result. The following extracts from one of the reports will serve to illustrate this:—

(a) It was noticed that three children, about eight years of age, were sitting at a desk; the form was 20 inches in height, the front edge of the desk was six inches from a perpendicular let-fall from the scholar's edge of the desk, so to reach the desk, which was 29 inches in height (scholar's edge), they had to bend over. These children were stooping over their books writing, their eyes two and a half inches or so from the books. One of these children I found to be suffering from a high degree of myopia; the other two children were, probably unconsciously, copying the example of the elder myopic child.

(b) The desks are those usually supplied for adults with forms as

A little earlier in the scene we find reference to the treatment of syphilis in Shakespeare's time.

> *Timon*: Give them diseases . . . .
> . . . . season the slaves
> For tubs and baths; bring down rose-cheeked youth
> To the tub-fast, and the diet.

The baths referred to were probably sweating baths, which were greatly used in the treatment of this disease. Jasper Torella, an eminent physician and Bishop of Justinia, who flourished in the early part of the sixteenth century, says that the cure of this disease, which he calls pudendagra, "depends, in the first place, upon diet and potions, in the second, upon bathing and local applications, and especially upon the use of the stove or sudatory; the hot-air or sweating bath; and, in the third place, on liniments containing a small proportion of quicksilver." The secretions of the skin were also systematically stimulated by sweating decoctions or sweating drinks, composed chiefly of sassafras and guaiacum—hence Pandarus says:

> "Till then I'll sweat, and seek about for eases."

The surgeons of those times adopted a particular diet in the treatment of the "lues," which was known and distinguished *par excellence* as *the* diet; and it is this diet, no doubt, which is referred to by Timon with the affix of the definite article. It seems to have been of a very moderate nature; in fact, its adoption might have been called, by those with a previously healthy appetite, fasting. This may explain the expression "tub-fast." Ambrose Paré orders: "Yet if the patient shall be weak, you may some hours before the unction, give him some gelley, the yolke of an egge or some broath made of meate boiled to pieces, but very sparingly, lest nature, intent upon the concoction of solid meats, or in great quantity, should bee drawn away from that which we intend."

Timon says to Apemantus farther on in the same scene: "I'll beat thee—but I would infect my hands," reminding us that in Shakespeare's time the secondary forms of the disease were erroneously thought to be contagious in the highest degree.

If Shakespeare disgusts the delicacy of the present age by the undisguised manner in which he treats this subject, it must be admitted that he presents it in a form little calculated to delude or mislead. On the contrary, he paints the morbid features of libertinism in all their truthful hideousness, from which a young man might derive the same kind of lesson as that of temperance which the Spartan Fathers endeavoured to teach their children, by presenting to their observation the repulsiveness of drunkenness in the person of their slaves. There is not among the many references to disease in Shakespeare's plays one that gives a better proof of the accurate medical knowledge of that wonderful dramatist.

I am, Sir, yours faithfully,
J. HENRY THOMPSON, M.B., B.Ch.R.U.I.

Croydon, Sept. 14th, 1908.

AN ANCIENT PICTURE.

To the Editor of THE LANCET.

SIR,—The engraving to which your correspondent refers is, I think, from the original picture in possession of the Royal College of Physicians of London. "It is painted by Robert Hannah, and was exhibited by him at the Royal Academy in 1848, and purchased by the College in 1869. [illegible] in the picture was copied by permission of the [illegible] Cornelius Jansen.

This picture was engraved by E[illegible] I believe, are now scarce, owing [illegible] which were many copies purchased by American visitors to the International Medical Congress in 1881.

I am, Sir, yours faithfully,
W. FLEMING.

London, S.W., Sept. 8th, 1908.

THE ALSAGER URBAN DISTRICT COUNCIL AND ITS MEDICAL OFFICER.

Dr. Henry Crutchley, medical officer of health of the Alsager District, is having a difference of opinion with his authority. It appears that he has been medical officer of health for 13 years at a salary of £20 per annum, one half of which is paid by the Local Government Board, and that during that time it had never been suggested that he was [illegible] other than an able and efficient [illegible] passed by the council requiring [illegible] reports, which hitherto had bee[illegible] Crutchley explained that he did not consider that personal attendance was necessary for the mere purposes of reading the report, but that he would be pleased to attend any meeting of the council when his advice was desired. Matters seem to have been left upon this reasonable basis until July 13th when a quarterly report was submitted through the clerk to the meeting of the council. On this occasion a resolution was passed that the council would not accept the report unless the medical officer attended "to give it personally." The resolution was forwarded by post to Dr. Crutchley by the clerk to the council, together with instructions that he must personally attend to present the quarterly report, and as the terms of the letter did not, in Dr. Crutchley's view, err on the side of civility it was not answered. On Sept. 8th, as Dr. Crutchley had not replied to the clerk's letter, and as his last report had not been accepted because it had not been verbally delivered, it was decided to advertise the post as vacant. The estimated population of the Alsager district is 2641, and it is perfectly clear to everybody that the quarterly report of the medical officer of such a district could be written in ordinary circumstances on half a sheet of notepaper, and that to require the medical officer to attend to read such a document to the authority, which already had it in its hands, is a ridiculous formality. Dr. Crutchley rightly considered that it would be necessary for him to attend whenever his advice was desired, and we cannot conceive why the Alsager urban district council should demand his presence on other occasions.

EARLY ENGLISH MEDICAL BOOKS.

To the Editor of THE LANCET.

SIR,—A medical work in English, a few years earlier than Boorde's "Breuvary of Health" (1552) mentioned by Mr. W. Kelly, was "The Englishman's Treasure with the True Anatomie of Man's Bodie," by Thomas Vicary. This was first published in 1548, but according to Mr. Sidney Young's "Annals of the Barber Surgeons" no copy of the first edition is now known to be extant. The earliest edition in the library of the British Museum bears date 1577. The popularity of this treatise may be judged from its attaining a ninth edition in 1641. A copy of this edition is in the library of St. Bartholomew's Hospital. Dr. F. J. Furnivall edited a reprint of this book (from the 1577 edition) for the Early English Text Society in 1888 (E. E. T. S., Extra Series, LIII.). Thomas Vicary was Serjeant Surgeon to King Henry VIII. and was five times Master of the Barber Surgeons Company. In the celebrated Holbein picture at Barbers' Hall he is represented receiving the charter from the King. He was also "Resident Surgical Governor" of St. Bartholomew's Hospital. Still earlier than the date of the first edition of Vicary's "Anatomie of the Bodie of Man"—namely, in 1528—there was published by T. Berthelet, at London, an edition of the famous "Regimen Sanitatis Salerni," with commentaries by Arnaldus de Villa Nova. "This boke techyng al people to governe them in helthe, is translated out of the Latyne tonge in to Englishe by T. Paynell." The commentaries only are in English. Further editions of this book were published in 1530, 1535, 1541, 1557, and 1575.

I am, Sir, yours faithfully,
A. L. MORETON.

St. Bartholomew's Hospital, Sept. 9th, 1908.

PS.—With reference to the questions concerning an ancient picture I have in my possession an engraving of the picture to which your correspondent [illegible] y Henry Lemon after Robert Hannah) was [illegible] by Lloyd Bros. of 22, Ludgate-hill, and dedic[illegible] of Hanover-terrace, Regent's Park, who presented the original picture to his friend, Joseph Hodgson, F.R.S., of Westbourne-terrace. Hodgson (1788–1869), it will be remembered, was a well-known Birmingham surgeon, and was P.R.C.S. in 1864.

PUBLIC HEALTH AND THE F.R.C.S. EDIN. EXAMINATION.

To the Editor of THE LANCET.

SIR,—Can any of your readers inform me as to the scope of public health as an optional subject for the F.R.C.S. Edin., also books recommended?

I am, Sir, yours *faithfully*,

THE EYESIGHT OF CHILDREN ATTENDING ARMY SCHOOLS IN INDIA.

(FROM AN INDIAN CORRESPONDENT.)

THE hygienic condition of army schools in India, particularly with regard to the question of vision, has recently been the subject of an inquiry. Specialists in ophthalmology were sent to the following stations to examine the vision of the children of British soldiers over seven years of age, and to give the parents concerned necessary information regarding the spectacles required where such were considered necessary:—Rawal Pindi, Peshawar, Nowshera, Ambala, Sialkot, Calcutta, Bareilly, Fyzabad, Lucknow, Meerut, Karachi, Mhow, Ahmednagar, Poona, Kirkee, and Bombay. The inspecting officers were also directed to report on the lighting of schools and the structural alterations necessary to improve it, together with the type of desks and seats used, with special reference to their adaptability for proper vision, and other subsidiary factors connected with the vision of school children. The result of these inspections is briefly as follows.

VISION.

This was tested by means of Snellen's test types, every child being required to read with each eye separately D—6 at 20 feet and D—0·6 at 10 inches. Any child who could not read the types was subsequently seen at hospital, where the refraction was ascertained under a mydriatic. The parents were then informed of the nature of the visual defect and advised as to what spectacles to procure. With few exceptions the parents provided the glasses at their own expense. The result of the examinations is shown in the following table:—

—	Actual numbers.	Percentages.
Total number examined	[illegible]	—
Number with defective vision	88	15
Hypermetropia	*55	11
Hypermetropic astigmatism	11	
Myopia	7	2
Myopic astigmatism	4	
Mixed astigmatism	7	1
Leucoma	2	—
Aphakia	1	—
Convergent squint	†18	3
Divergent squint	‡1	
Trachoma	15	—
Nystagmus	1	—
Dislocation of lens	1	—

* Includes 18 cases of squint.
† Hypermetropia 15; leucoma 2, aphakia, 1. ‡ Hypermetropia.

Slight cases of hypermetropia with 6/6 vision, in which muscular equilibrium was perfect and which did not require correction by glasses, are not shown amongst those with defective vision. In one case, a child with myopic astigmatism was found to be wearing + 1 spheres. In another case a child was found with 1/60th vision (each eye) due to partial dislocation of the lenses. In several cases it is remarked that children who were considered wanting in intelligence became quite bright and intelligent after the supply of glasses. The percentage of cases of myopia is much the same as is usually found in school children of the age examined. The large majority of children seen were below 12 years of age, whereas myopia attains its greatest frequency between 12 and 18 years.

It will be noticed that 19 cases of squint were found. According to Worth, 75 per cent. of cases of unilateral squint appear before the end of the fourth year, and in 53 per cent. of alternating cases the deviation is seen before the end of the second year. This being so, it appears desirable that the eyes of all children should be examined by a medical officer for early signs of squint and other visual defects before school attendance is commenced.

LIGHTING.

With the exception of the schoolrooms at Karachi and Colaba, the lighting in all cases was found to be defective and in some instances very bad, notably the schools for adults and elder children at Calcutta, Fyzabad, Ahmednagar, Rawal Pindi (cavalry) and Mhow (cavalry), and the infants' school at Meerut. The rooms referred to at Ahmednagar and Mhow are described as very dark and ill-ventilated. In some schools the lighting was so defective that the inspectors found that lamps had to be used on dull mornings. The defective lighting was found to be due chiefly to the fact that most schools were not built as such, but are old barrack-rooms re-appropriated and so constructed that to improve the lighting is a difficult matter. The defects in lighting have been brought to notice and representations made indicating the structural alterations necessary to improve it so as to render the building suitable for school purposes. In the majority of cases this can be done at small expense by enlarging and increasing the number of clerestory windows, reducing the woodwork in windows, and increasing the glass area generally. The necessity for so arranging matters as to insure a larger glass area on the side (left side of the pupils) from which the major portion of the light enters has been pointed out. It has been recommended that sunshades should be removed from all clerestory windows on the north side and that those over other windows should be hinged so that they may be raised during the winter months. Attention has been drawn to the desirability of colour-washing the walls of schools pale green and a recommendation has been made that an order should be issued and embodied in regulations to this effect. Softer light would be obtained and glare from the walls would be prevented. In nearly all schools the walls are at present whitewashed.

DUTIES OF TEACHERS IN CONNEXION WITH EYESIGHT.

In addition to the defective lighting the report states that in many cases the light is not properly directed on to the desks. In some cases children are to be seen sitting facing the glare from windows, while in others they have their backs to the light, or the light comes from the right. This incorrect placing of desks is due in some cases to ignorance on the part of teachers of the fact that the preponderance of light should always come from the "left" of the scholars; in other cases it is due to inability on the part of schoolmasters so to arrange the desks as to obtain the above effect, as a result of narrowness of the rooms, length of desks, or difficulty in arranging classes and blackboards so that a side light from the left is obtained. Considering this, and the fact that 19 cases of squint were found, of which some had not been sent to hospital for treatment, it would appear that army schoolmasters fail to realise their responsibilities in preventing the deterioration of vision of the children who are constantly under their observation. With a view to rectifying this a short list of instructions detailing "the duties of schoolmasters in connexion with eyesight" has been drawn up.

DESKS AND SEATS.

In all schools (with the exception of five desks at Rawal Pindi and a few at one or two other stations) the desks and seats are very unsuitable for children. Those supplied for elder children are in nearly all cases too high, being intended for men. The result is that children seated at such desks assume faulty positions: the feet hang some distance from the ground or rest in an awkward position on foot-rails, and the weight is supported partly on the left arm and partly on the chest which is pressed against the desk. In all cases the seats are too broad; in very few instances have back-rests been provided, and even when present they slope at too great an angle. The seats are forms and are placed at varying distances from the desks, the result being that to reach the desk the body is bent forward and the head falls towards the desk as the muscles of the neck become tired. The eyes being too near the book accommodation and convergence are strained, the eyeball is compressed by the recti muscles, and myopia or strabismus is liable to result. The following extracts from one of the reports will serve to illustrate this:—

(c) It was noticed that three children, about eight years of age, were sitting at a desk; the form was 20 inches in height, the front edge of the desk was six inches from a perpendicular let fall from the scholar's edge of the desk, so to reach the desk, which was 22 inches in height (scholar's edge), they had to bend over. These children were stooping over their books writing, their eyes two and a half inches or so from the books. One of these children I found to be suffering from a high degree of myopia; the other two children were, probably unconsciously, copying the example of the elder myopic child.

(d) The desks are those usually supplied for adults with forms as

Communications, Letters, &c., have been received from—

An original and novel feature of "THE LANCET General Advertiser," is a Special Index to Advertisements on pages 2 and 4, which not only affords a ready means of finding any notice but is in itself an *additional* advertisement.

Advertisements (to insure insertion the same week) should be delivered at the Office not later than Wednesday, accompanied by a remittance.

Answers are now received at this Office, by special arrangement, to advertisements appearing in THE LANCET.

The Manager cannot hold himself responsible for the return of testimonials, &c., sent to the Office in reply to advertisements; copies only should be forwarded

Cheques and Post Office Orders (crossed "*London* and Westminster Bank, Westminster Branch") should be made payable to the Manager, Mr. CHARLES GOOD, THE LANCET Office, 423, Strand, London, to whom all letters relating to Advertisements or *Subscriptions should* be addressed.

THE LANCET can be obtained at all Messrs. W. H. Smith and Son's and other Railway *Bookstalls throughout* the United Kingdom. Advertisements are also received by them and all other Advertising Agents.

Agent for the Advertisement Department in France—J. ASTIER, 31, Rue Bapst, Asnieres, Paris.

treaties. Then Spain, France, Italy, and Norway with nine; Belgium, Denmark, and Sweden with eight; the United States of America with seven such treaties; and other nations with a smaller number. Various diagrams and "graphics" illustrate all these facts and they seem to point the moral and to explain the significance of the whole exhibition and such similar international efforts. Obviously exhibitions are a work of peace. Without peace, science, especially preventive medicine and sanitary science, would make but scant progress.

A few steps further and the very complete and well-arranged French drug section is reached to which a very brief allusion has been already made. Here many old and well-known friends meet the eye such as the papier Rigollot form of mustard poultice and the ever-popular Tamar Indien, the effective laxative that looks and tastes like a sweetmeat. The Clin laboratories were founded in 1864 by Dr. Clin who obtained the Prix Montyon. Here have been produced the fer Rabuteau and the bromide of camphor much used by Professor Charcot and Professor Bourneville. More recently, under the management of Messrs. F. Comar et Fils et Cie., some modern drugs have been put on the market and are now exhibited. There are, for instance, various cacodylates and metharsinates which permit the administration of large doses of arsenic; and the new salicylarsinate of mercury. Opposite this exhibit Messrs. Berlaut-Blancard Frères have specimens of catgut prepared according to the interesting method devised by M. J. Triollet and described in the annals of the Pasteur Institute. A catgut used for surgical purposes must be supple but if sterilised with dry heat it will be brittle. The catgut exhibited is rolled round a bobbin and placed in a receptacle containing acetone and sterilised at 120° C. for 40 minutes. When this is done the receptacle is not opened but simply turned upside down. A little sterilised water which had been placed inside the bobbin is spilt, and as it reaches the catgut only after the sterilisation is over helps to soften it without great injury to its qualities. The process is ingenious but difficult to explain in a few words. There are also in this section the exhibits from the works of Poulenc Frères that date back to a small drug store established in 1827. They now produce a great variety of chemicals used in pharmacy, science, photography, *metallurgy, and also in the china, earthenware, and glass* industries. Of special interest is the fact that they have been appointed the sole selling agents for the preparations of the Pasteur Institute at Lille. These consist of Dr. Calmette's anti-venom serum used in cases of snake bites and the powdered antitetanic serum for dressing wounds, together with the recently discovered tuberculin test for the ophthalmo-reaction of tuberculosis.

Of other French firms having their exhibits close at hand, we may mention Messrs. Roure-Bertrand Fils and other *great distillers from Grasse who make* extracts from flowers for the manufacture of scents. Then in a glass case there is a mysterious pile of small white paper tubes looking like a pyramid made with collapsed and half-empty cigarettes. These are cigarette papers but they contain and shield from the air and its microbes "Le Negri" sterilised toothpicks. As something toothsome there is to be seen just opposite the phosphatine Fallière, a food for young children and invalids, consisting of sterilised flour, with a slight addition of phosphates, and some finely flavoured chocolate. Boiled with milk we have here something that is really delicate and pleasant, while it is a useful food for the weak and the young.

In regard to nutritious substances that constitute at the same time an epicurean delicacy we have in the horticultural and gardening section a very graphic exhibit of those Parisian mushroom beds which produce the small, white, firm nut- or button-shaped mushroom without which a real chef would not deign to prepare a meal. Not only are the actual beds there with the mushrooms growing on them, but there are many photographs of those innumerable underground passages which honeycomb a great part of Paris. Here the beds are built up and here these gastronomic delicacies are grown and then exported to many foreign countries. The details in regard to a still greater delicacy are also given in this section and we see where and how truffles are grown. Photographs also are suspended to the wall of that modern Tantalus, the pig, which is ever digging the truffles out of the ground but is forced to drop them before it has time to enjoy a bite or two. There is a great deal to be seen relating to technical instruction for the production of aliments, butter, cheese, fruits, and the preservation of fruits. Indeed, for food and for wines France has naturally much that must interest British subjects since we are the best customers of the French cultivator or vineyard proprietor.

THE INTERNATIONAL CONGRESS ON TUBERCULOSIS AT WASHINGTON.

(FROM A SPECIAL CORRESPONDENT.)

IT will, perhaps, be useful to describe a little more in detail the way in which the subjects for discussion will be arranged in the seven sections which I enumerated last week.[1] The meetings may be the occasion of no such piquant episode as characterised the meeting in London when Professor Koch startled the medical world by his crisp statements as to the want of infectivity of the bovine tubercle bacillus for the human subject and the converse. It is evident, however, from the provisional programme which has reached us that in each of the seven sections questions of great scientific and practical interest will be brought forward. There will, of course, be some overlapping of the work of the different sections but the arrangements have been well thought out and the material at the disposal of the committee well organised.

As a kind of echo from the British Congress we have as the first item on the list of subjects for discussion Variations of the Tubercle Bacillus, especially as regards Virulence, a subject on which a good deal of information has been collected during the last few years, and we may anticipate a somewhat lively discussion if the "stalwarts" from different camps settle down to their work. Immunity in tuberculosis, mixed and concomitant infections, the pathological characters of congenital tuberculosis and of tuberculosis in infancy and childhood will all receive attention, whilst bearing on the question of the variations of the tubercle bacillus, the lesions, especially the primary lesions, produced by this organism are to be considered, as are also the sources and channels of infection, especially the lungs, whether from without or from surrounding organs and tissues. The work of Section II. is divided into three symposia: In the first the diagnosis and Treatment of Early Cases of Tuberculosis in which the use of x rays, the opsonic index, and the conjunctival and cutaneous tuberculin reactions will probably come in for special consideration. A number of other subjects, such as diet in pulmonary tuberculosis and the physiological effects of residence in high altitudes upon consumption, will also be discussed. In the second symposium tuberculin and its derivatives and the serum treatment are to be considered, whilst in the third sanatoriums, hospitals, dispensaries, and home treatment for tuberculosis are set down for discussion. For this *part of the section* a programme of most useful papers has been prepared and a good many of the State and municipal delegates will probably spend a considerable part of their time in following the discussion in this section, though the counter-attraction of some of the other sections will be very great.

In Section III., that of Surgery and Orthopædics, tubercle of every organ of the body is to be considered and the surgical treatment of tuberculosis and such questions as the Prevention, Diagnosis, and Surgical Treatment of Tuberculous Sinuses and Abscess Cavities; Acute Forms of Abdominal Tuberculosis; Indications for Operative Treatment for Bone Tuberculosis; and Wright Vaccination being representative headings of discussion in this section. In Section IV. we have a regular syllabus which reads almost like the contents page of a "work by many authors" on tuberculosis in children. The thing that will strike anyone on going over this syllabus is that three weeks, even if the discussion is continued the whole time, is a very short period in which to tackle such a large number of questions. The same remark applies to Section V., but it is seen in this case that the main questions to be tackled will form a very small portion of the official programme, as a good many of the points laid down are already accepted and will probably lead to a very little discussion, whilst on others very little information can possibly be forthcoming. At the same bullous or vesicular disorders. Poisons generated from within account for the itching in severe jaundice and in Hodgkin's disease. In like manner we may explain the itching occasionally met with in women at or after the menopause, a vaso-motor disturbance connected with the cessation of a long existent and important function and not improbably due to a degree of auto-intoxication from deficient elimination.

---

[1] THE LANCET, Sept. 12th, p. 840.

While itching may, as we have seen, be experienced over large tracts of the surface, it is quite as frequently restricted to certain localised areas, and examples of this constantly come under our notice. One of the most common is that known as pruritus ani, an aggravating, sometimes an intolerable, irritation about the seat. Men are much more liable to this than are women, or at least more of our patients who complain are of the male sex. Some are sedentary and studious, others active, restless, or nervous. It is in all cases a symptom, but we cannot in every one determine with exactitude the latent cause. Thread worms in the rectum, piles (external or internal), fissures, prostatic disorders may, one or all, be incriminated. But in many the liver is assuredly at fault. Not always primarily, as one may have to go further back and discover in some cardiac trouble the source of the portal repletion or congestion. A simple catarrhal state of the hepatic ducts may be traced in not a few instances. Again, itching at the anus may be a symptom of cancer within the pelvis. In fact, we have in many otherwise obscure cases a dilated and tortuous condition of the submucous veins of the rectum, which finds its expression as itching at the anus. The scratching indulged in leads to a white, sodden, and thickened condition of the neighbouring integument, accompanied with heat and moisture, intensifying the discomfort. You are all sufficiently familiar with the characters assumed, which require no further elaboration.

Another distressing variety is that which affects the vulva. The labia become swollen, leathery, and hard, and the patient has often a worn worried expression, owing to lack of sleep, and also to the difficulty she has in refraining from rubbing and scratching the parts in public. Here one must be on the outlook for glycosuria, not necessarily diabetic, as this form is perhaps more aggressive in stout, gouty women than in the subjects of veritable diabetes mellitus. It is thus often eminently curable. But it may occur quite apart from saccharine urine, and some of the most severe and obstinate examples I have met with have been in women approaching the menopause, whose urine did not show a trace of glucose.

Lastly, there are some minor forms. One occurs under the fourth toe, and between it and the adjoining ones, and is particularly troublesome at night when the stockings are removed. Though the mucous surfaces themselves hardly itch, yet this is now and again observed within the meatus of the ear, inside the nostril, and on the surface of the tongue, but scarcely to such an extent or lasting so long as to need any treatment.

There are but a few points in the diagnosis of itching which call for remark. In all cases of generalised itching the possible existence of scabies, or the presence of insect pests, or the chance of the irritation having been started by plants must ever be borne in mind. No station in life, no correctness of habits or apparent care as to the person, should be allowed to prejudice our judgment. From circumstances of the nature of which we cannot be ourselves cognisant, and without even the knowledge of the sufferer, he or she may have been exposed to the chance of contracting the parasites, or have been in contact with the noxious leaf. In all our inquiries the utmost tact requires to be exercised, and we should omit nothing in our examination so as to arrive at the knowledge which will enable us to afford relief.

In the treatment of itching one cardinal proviso emerges. One cannot treat it solely as a substantive lesion without risk of failure. All the circumstances must be taken into account. The cause has to be diligently sought for, the locality considered, the individual studied, and accessory conditions given due weight. In the cases where there is itching without definite integumentary disturbance, as in senile pruritus apart from pediculi, some medicated soaps will be found useful. Menthol soap is that most frequently applicable. It acts by substituting the sensation of cold for that of itching and in mild instances often gives prompt relief. Nicotine as nicotiana soap, as recommended by Taenzer and Unna, deadens the hyperæsthesia of the nerve terminals in the epidermis, but it should be employed with caution and never over wide areas, else toxic symptoms may arise. Naphthol soap is indicated in similar states, and not only lessens undue sensitiveness but tends to ward off the attack of parasitic insects. When the surface is dry with slight desquamation of branny particles warm baths taken under blood heat and containing some freshly prepared starch jelly, followed, after gentle drying with a soft bath towel, by the inunction of glycerine of starch thinned down by the addition of a double proportion of glycerine, has proved extremely valuable in my hands in climacteric cases. Should these measures prove insufficient we can in most cases of pure senile pruritus obtain a permanent cure by giving a course of subcutaneous pilocarpine injections administered each night and extended over a couple of weeks. This usually restores the sweat gland system to functional activity and with the re-establishment of cutaneous exhalation the trouble ceases. The vests worn next the skin should be of silk, Indian gauze, or linen, and over these thicker and warmer ones may be put according to the season of the year or in the case of those whose circulation requires additional protection. When pediculi are discovered or their presence is strongly suspected, besides washing with carbolic or storax soap, accompanied by a thorough change of body and bed linen, the soil may be rendered unattractive by directing the patient to wear next the skin, day and night, a muslin or flannel bag containing fragments of rock sulphur. The heat of the body slowly volatilises the sulphur, it is converted into sulphurous acid by the oxygen of the air, and so provides an atmosphere round the person which acts as an efficient deterrent to the onslaughts of the pediculus. It must be borne in mind that the pediculus vestimentorum occasionally attaches its ova to the lanugo hairs; to prevent these hatching and so germinating a fresh colony it is well to rub some ordinary paraffin oil over the trunk and limbs or to anoint with unguentum staphisagriæ for a few days. Neglect of this is the source of the belief in spontaneous generation of lice and simply explains why the insects so constantly reappear, though all other precautions have been taken.

We cannot dissociate the treatment of itching in eczema from that demanded by the conditions of the disease in each actual case, but as far as possible we ought to combine antipruritic with anti-eczematous remedies. In eczema the horny layer is soft and porous and thus deficient in its natural power of resistance. Since it is in the dry and the chronic forms of eczema in general, and again in all varieties immediately preceding or subsequent to apparent cure, that itching most markedly asserts itself, two indications for our guidance emerge. One of these is that the new and delicate epidermis dries very rapidly, and hence minute fissures form in it, and by these cracks the atmospheric air gains access to the deeper strata and so acts as an irritant to the spongy cells. It is in this layer of cells that the cutaneous sensory nerve fibrils terminate and the unhealthy state of the skin renders these specially sensitive. Thus it follows that lotions, always the simplest and most agreeable preparations to employ, which in drying deposit an impalpable and neutral powder, take the premier place in our armamentarium. The coating in process of formation insinuates itself into the chinks, and not only occludes them but at the same time promotes exsiccation and so diminishes itching. Calamine lotion with the addition of a drachm of boric or in some cases of carbolic acid, here proves very valuable. In the essentially dry forms perhaps even more useful is one recommended by Boeck of Christiania, which possesses likewise astringent and sedatives properties:—

Talci	āā 100 0
Pulv. amyli	
Liq. plumbi subacetatis dil...	
Sol. acidi borici in aquâ 1%...	
Glycerini	40 0
Aq. camphoræ	250 0

This should be well shaken before being used, as it is apt to cake owing to the starch, and painted uniformly on with a stiffish paste brush since the ordinary camel hair one is too soft and readily clogs. The lotion will relieve the itching for about four or more hours and can then be re-applied.

treaties. Then Spain, France, Italy, and Norway with nine; Belgium, Denmark, and Sweden with eight; the United States of America with seven such treaties; and other nations with a smaller number. Various diagrams and "graphics" illustrate all these facts and they seem to point the moral and to explain the significance of the whole exhibition and such similar international efforts. Obviously exhibitions are a work of peace. Without peace, science, especially preventive medicine and sanitary science, would make but scant progress.

A few steps further and the very complete and well-arranged French drug section is reached to which a very brief allusion has been already made. Here many old and well-known friends meet the eye such as the papier Rigollot form of mustard poultice and the ever-popular Tamar Indien, the effective laxative that looks and tastes like a sweetmeat. The Clin laboratories were founded in 1864 by Dr. Clin who obtained the Prix Montyon. Here have been produced the fer Rabuteau and the bromide of camphor much used by Professor Charcot and Professor Bourneville. More recently, under the management of Messrs. F. Comar et Fils et Cie., some modern drugs have been put on the market and are now exhibited. There are, for instance, various cacodylates and metharsinates which permit the administration of large doses of arsenic; and the new salicylarsinate of mercury. Opposite this exhibit Messrs. Berlaut-Blancard Frères have specimens of catgut prepared according to the interesting method devised by M. J. Triollet and described in the annals of the Pasteur Institute. A catgut used for surgical purposes must be supple but if sterilised with dry heat it will be brittle. The catgut exhibited is rolled round a bobbin and placed in a receptacle containing acetone and sterilised at 120°C. for 40 minutes. When this is done the receptacle is not opened but simply turned upside down. A little sterilised water which had been placed inside the bobbin is spilt, and as it reaches the catgut only after the sterilisation is over helps to soften it without great injury to its qualities. The process is ingenious but difficult to explain in a few words. There are also in this section the exhibits from the works of Poulenc Frères that date back to a small drug store established in 1827. They now produce a great variety of chemicals used in pharmacy, science, photography, metallurgy, and also in the china, earthenware, and glass industries. Of special interest is the fact that they have been appointed the sole selling agents for the preparations of the Pasteur Institute at Lille. These consist of Dr. Calmette's anti-venom serum used in cases of snake bites and the powdered antitetanic serum for dressing wounds, together with the recently discovered tuberculin test for the ophthalmo-reaction of tuberculosis.

Of other French firms having their exhibits close at hand, we may mention Messrs. Roure-Bertrand Fils and other great distillers from Grasse who make extracts from flowers for the manufacture of scents. Then in a glass case there is a mysterious pile of small white paper tubes looking like a pyramid made with collapsed and half-empty cigarettes. These are cigarette papers but they contain and shield from the air and its microbes "Le Negri" sterilised toothpicks. As something toothsome there is to be seen just opposite the phosphatine Fallière, a food for young children and invalids, consisting of sterilised flour, with a slight addition of phosphates, and some finely flavoured chocolate. Boiled with milk we have here something that is really delicate and pleasant, while it is a useful food for the weak and the young.

In regard to nutritious substances that constitute at the same time an epicurean delicacy we have in the horticultural and gardening section a very graphic exhibit of those Parisian mushroom beds which produce the small, white, firm nut- or button-shaped mushroom without which a real chef would not deign to prepare a meal. Not only are the actual beds there with the mushrooms growing on them, but there are many photographs of those innumerable underground passages which honeycomb a great part of Paris. Here the beds are built up and here these gastronomic delicacies are grown and then exported to many foreign countries. The details in regard to a still greater delicacy are also given in this section and we see where and how truffles are grown. Photographs also are suspended to the wall of that modern Tantalus, the pig, which is ever digging the truffles out of the ground but is forced to drop them before it has time to enjoy a bite or two. There is a great deal to be seen relating to technical instruction for the production of aliments, butter, cheese, fruits, and the preservation of fruits. Indeed, for food and for wines France has naturally much that must interest British subjects since we are the best customers of the French cultivator or vineyard proprietor.

THE INTERNATIONAL CONGRESS ON TUBERCULOSIS AT WASHINGTON.

(FROM A SPECIAL CORRESPONDENT.)

IT will, perhaps, be useful to describe a little more in detail the way in which the subjects for discussion will be arranged in the seven sections which I enumerated last week.[1] The meetings may be the occasion of no such piquant episode as characterised the meeting in London when Professor Koch startled the medical world by his crisp statements as to the want of infectivity of the bovine tubercle bacillus for the human subject and the converse. It is evident, however, from the provisional programme which has reached us that in each of the seven sections questions of great scientific and practical interest will be brought forward. There will, of course, be some overlapping of the work of the different sections but the arrangements have been well thought out and the material at the disposal of the committee well organised.

As a kind of echo from the British Congress we have as the first item on the list of subjects for discussion Variations of the Tubercle Bacillus, especially as regards Virulence, a subject on which a good deal of information has been collected during the last few years, and we may anticipate a somewhat lively discussion if the "stalwarts" from different camps settle down to their work. Immunity in tuberculosis, mixed and concomitant infections, the pathological characters of congenital tuberculosis and of tuberculosis in infancy and childhood will all receive attention, whilst bearing on the question of the variations of the tubercle bacillus, the lesions, especially the primary lesions, produced by this organism are to be considered, as are also the sources and channels of infection, especially the lungs, whether from without or from surrounding organs and tissues. The work of Section II. is divided into three symposia: In the first the diagnosis and Treatment of Early Cases of Tuberculosis in which the use of x rays, the opsonic index, and the conjunctival and cutaneous tuberculin reactions will probably come in for special consideration. A number of other subjects, such as diet in pulmonary tuberculosis and the physiological effects of residence in high altitudes upon consumption, will also be discussed. In the second symposium tuberculin and its derivatives and the serum treatment are to be considered, whilst in the third sanatoriums, hospitals, dispensaries, and home treatment for tuberculosis are set down for discussion. For this part of the section a programme of most useful papers has been prepared and a good many of the State and municipal delegates will probably spend a considerable part of their time in following the discussion in this section, though the counter-attraction of some of the other sections will be very great.

In Section III., that of Surgery and Orthopædics, tubercle of every organ of the body is to be considered and the surgical treatment of tuberculosis and such questions as the Prevention, Diagnosis, and Surgical Treatment of Tuberculous Sinuses and Abscess Cavities; Acute Forms of Abdominal Tuberculosis; Indications for Operative Treatment for Bone Tuberculosis; and Wright Vaccination being representative headings of discussion in this section. In Section IV. we have a regular syllabus which reads almost like the contents page of a "work by many authors" on tuberculosis in children. The thing that will strike anyone on going over this syllabus is that three weeks, even if the discussion is continued the whole time, is a very short period in which to tackle such a large number of questions. The same remark applies to Section V., but it is seen in this case that the main questions to be tackled will form a very small portion of the official programme, as a good many of the points laid down are already accepted and will probably lead to a very little discussion, whilst on others very little information can possibly be forthcoming. At the same which have proved most efficient in my hands Should these disappoint you, and I warn you they will—though I trust not frequently—do so, then try some one or other of those suggested in your text-books. All that it is in my power here to accomplish is to lay down the broad lines on which to advance, bearing in mind that there are numerous other paths available to attain the goal.

---

[1] THE LANCET, Sept. 12th, p. 840.

A CASE OF EMBOLIC (? THROMBOTIC) ATELECTASIS OF THE MIDDLE AND LOWER LOBES OF THE RIGHT LUNG; SURVIVAL.

By H. BATTY SHAW, M.D. LOND., F.R.C.P. LOND.,
PHYSICIAN TO UNIVERSITY COLLEGE HOSPITAL, AND ASSISTANT PHYSICIAN TO THE BROMPTON HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST;
AND
EDRED M. CORNER, M.A., M.B., M.C. CANTAB., F.R.C.S. ENG.,
SURGEON IN CHARGE OF OUT-PATIENTS, ST. THOMAS'S HOSPITAL, AND SURGEON, HOSPITAL FOR SICK CHILDREN, GREAT ORMOND-SRTEET.

WE publish an account of this case because of the unusually large amount of the right lung which had collapsed as a result of embolic (? thrombotic) partial occlusion of the pulmonary artery and because we are unable to find any account of a similar occurrence with survival.

The patient, a gentleman who was emphysematous and had been suffering from phlebitis of the legs for the previous five or six years, came under the care of one of us on April 16th, 1907. The patient had not been feeling well since February of the same year and had found it difficult to perform his duties. When he came under observation there were signs of phlebitis, more especially of the right leg; the usual methods were adopted for the treatment of this condition. The local symptoms abated and it was felt that with a little longer rest in bed the phlebitis would disappear. On May 2nd, however, the patient was seized with very severe pain in the right chest, with dyspnœa, slight hæmoptysis, and some cyanosis; the temperature rose to 101·6° F. Previous to this date the temperature had been subnormal, except on the evenings of April 29th and 30th when it reached 99° and 99·8°. Examination of the chest revealed no signs of involvement of either lung. So susceptible was the patient to pressure over the whole of the right side and to movement of the right shoulder that a tentative diagnosis was made of "muscular rheumatism." The maximum impulse of the heart was ill defined but the area of dulness presented no abnormalities other than those which might be expected from moderate emphysema; the stomach note was found to reach higher in the left axilla than is usually the case. On May 3rd the pain in the chest was still very marked, the ordinary liver dulness was increased a little upwards, and the breath sounds of the right chest were weak, more especially over that part corresponding with the middle and lower lobes. The blood-stained expectoration was found to be free from tubercle bacilli but contained several varieties of cocci and bacilli (Gram-positive and Gram-negative). On May 4th, 5th, and 6th the pain was still present but less in degree; it failed to respond to the action of aspirin, &c. On the 7th fluid was suspected at the base of the right chest as the dulness had gradually extended upwards to the spine of the scapula behind and to the second rib in front. (Diagrams I. and II.) Movement of the right chest was very limited and the breath sounds and vocal fremitus over the dull area were almost suppressed. On the 8th an exploratory puncture was made of the right chest and two ounces of yellow blood-stained fluid were removed. Each cubic millimetre of the fluid contained 560,000 red corpuscles and 31,000 white corpuscles. The analysis of the latter showed small lymphocytes 48·2 per cent., large lymphocytes 11·8 per cent., polymorphonuclear cells 32·4 per cent., and endothelial cells 7·6 per cent.; no organisms could be detected in film preparations and 10 cubic centimetres of the fluid injected into a guinea-pig gave no evidence of tuberculosis at the end of a month. On May 9th an attempt was made to remove the rest of the fluid, using a larger aspirating needle. No fluid, however, could be obtained and the lung could be felt not far removed from the chest wall. A little doubtful friction sound could be heard at the right base. On the 19th the signs of dulness over the greater part of the right lung remained unchanged and there was increased difficulty in locating the exact position of the heart.

Diagram I

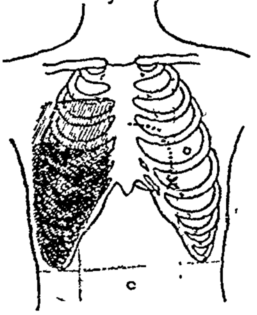

Diagram II

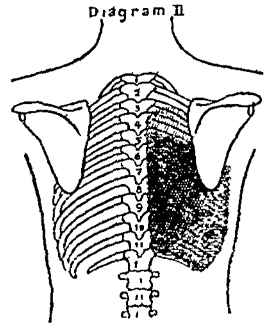

From this date onwards no active measures were taken, the patient being kept in bed and allowed to move as little as possible. The signs of dulness over the right chest gradually underwent some reduction from above; tubular breathing and increase of vocal resonance developed in the neighbourhood of the right inferior scapular angle; the movement of the right chest remained limited, although the pain had disappeared. The temperature had reached normal by May 10th but again rose on the 13th and remained slightly elevated during the rest of his stay in the nursing home. The pulse which before the episode of May 2nd had been normal rose to 112–120 on occasions of extra pain; ordinarily it was 80–84. On May 27th, owing to progressive loss of weight and the maintenance of the elevated temperature, it was decided that the patient should be removed from the "home" and be placed under the care of Dr. E. T. M. Tunnicliffe of North Finchley. The same methods were continued combined with open-air treatment. Eructation which had all along been a source of annoyance to the patient was alleviated by dietetic and medicinal measures. On June 16th the phlebitis, which had subsided, again supervened in the neighbourhood of the right popliteal space but subsided in a few days and there has been no further recurrence since. On the 29th the patient was again examined and the following observations were made. The pulse and temperature were normal and the general condition was satisfactory, though there was some shortness of breath on exertion. On moderately hard percussion of the right chest the dull area was limited above by a line drawn from the fourth rib in the right nipple line to the right inferior scapular angle; the same area of dulness was limited below, not by a line corresponding with the costal margin, but by a curved line, with the concavity downwards, which reached from the sixth rib in the right nipple line to the eleventh rib behind in the scapular line. Over this area the breath sounds were practically absent. The area of cardiac dulness was still very obscure, a slight cardiac impulse could be felt occasionally in the fourth space in the left nipple line; the stomach note was still unusually elevated. (Diagrams III. and IV.)

Diagram III

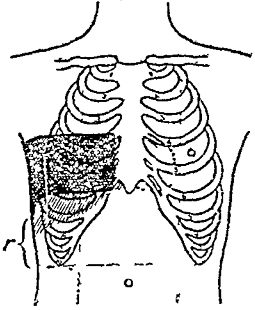

Diagram IV

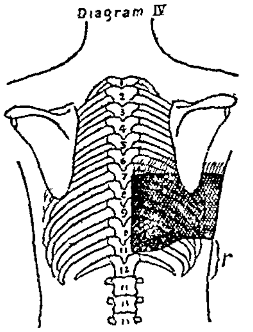


The patient was allowed to leave for another part of the country and ultimately went to Dresden, being free from pain

Tuberculosis in Cattle.

Tuberculosis in cattle is not only dangerous to the health of the community but may lead to financial loss on the part of the public. A largely attended meeting of the Lancashire Farmers' Association was held just lately at Preston, which pledged itself to use every effort to put in force the prices recommended by the milk committee for the Michaelmas milk contracts. It need not be said that they are higher than the old ones. Another matter was also the subject of much discussion—namely, who must pay if an animal bought by a butcher which has been guaranteed as free from disease and fit for human food is found to be diseased. After some vigorous speeches the following motion was unanimously agreed to:—

> That while sympathising with butchers in the hardships inflicted on them by the confiscation of tuberculous carcasses *bonâ fide* bought at a fair market price and apparently healthy, the proposal to throw the whole responsibility on the farmers was unfair, and that farmers, butchers, and auctioneers, should combine to enforce their demand for a reasonable scheme of compensation from public funds when carcasses that have shown no previous symptoms of being diseased are condemned in the public interest.

If all possible care has been taken by the farmer to ascertain whether the animal sold is healthy or not it does seem hard if he has to bear all the loss. This, of course, is quite a different case from that of the "slink butcher," whose business it is to deal in diseased meat, sometimes, no doubt, in collusion with a dishonest farmer.

Sept. 15th.

NEWCASTLE-UPON-TYNE.

(FROM OUR OWN CORRESPONDENT.)

Changes in the Staff of the Royal Victoria Infirmary.

Dr. George Redmayne Murray has been elected an honorary consulting physician on resigning his position as physician to the infirmary. Dr. Murray leaves Newcastle this week to take up his duties as Professor of Systematic Medicine in the Victoria University of Manchester and physician to the Manchester Royal Infirmary. Dr. W. E. Hume has been elected a physician to the infirmary. Dr. Hume was senior house physician to the Royal Infirmary until 1907, and was elected an honorary assistant physician at the beginning of the present year.

Presentation and Dinner to Dr. Murray.

Dr. Murray was entertained to dinner on Sept. 3rd by his colleagues at the College of Medicine and Royal Victoria Infirmary on the occasion of his approaching departure for Manchester in order that they might offer him their congratulations and wish him success in his new sphere of work. Sir G. H. Philipson was in the chair, and in proposing Dr. Murray's health congratulated him very heartily on his appointments, and assured him that the good wishes of all present, and of many others besides his immediate colleagues, would accompany him to Manchester, where they hoped he would spend many useful and happy years. Dr. David Drummond, in supporting Sir G. H. Philipson, referred to the loss which he and his colleagues would sustain by Dr. Murray leaving Newcastle, but at the same time they could not but feel gratified that one of their number had been invited to accept the important positions which Dr. Murray was about to occupy. He offered Dr. Murray the congratulations and good wishes of himself and his colleagues and begged his acceptance of the piece of silver which he had been asked to present to him as a memento of those years of his professional life which he had spent in Newcastle. Dr. Murray, in reply, said that while he appreciated to the full the goodwill and kindliness of feeling on the part of his colleagues which had prompted that meeting, he nevertheless found it exceedingly difficult to give expression to the thoughts and feelings of which he was at the moment the subject. It was with no light heart that he was leaving the town where he was born and with which he had so many close associations. He recognised the honour which had been done him when he received the invitation to go to Manchester, but it was only after very anxious thought and consultation with his professional friends that he had decided that he ought to sacrifice his personal inclinations to what he thought was, in the circumstances, a duty. He was, however, very glad indeed that he would not altogether sever his professional connexion with Newcastle. The position of consulting physician which the infirmary had done him the honour to confer upon him and the honorary membership of the College which had been offered him would, he believed, give him the chance, which he was most anxious to take, of retaining a real and active interest in the work of the medical world of Newcastle. For many reasons he was sorry that he was leaving Newcastle at the present time. Changes were taking place, or were about to take place, which were bound to have a most important influence on the future of medical education in Newcastle. The present was the great opportunity of the provincial schools. London, for well-known reasons, had been steadily ceasing to attract students for the past ten years. Decentralisation of medical education was taking place, and that very rapidly indeed. Several of the larger provincial cities and towns had realised this and had made full use of the opportunity. He hoped that Newcastle would not fail to follow the lead of other provincial schools and provide facilities such as they had provided. The present was the opportunity and one which it was vitally important should not be lost. Many problems were involved, but of one, he thought, he was competent to speak. He wished very earnestly to impress upon the authorities of the College and of the infirmary the necessity for a closer union between the two institutions, a union which was equally necessary in the interests of the students, the patients, and of medical research. He wished them especially to realise the necessity for bringing the departments of pathology and bacteriology in the College and infirmary each under the control of one man respectively. The present position was anomalous. The student's opportunities were wasted through no fault of the latter. The patients could not derive the benefit which they should from the present-day knowledge of pathology so long as things remained as they were. It should not be a difficult matter, seeing that many members of the staff of the College held positions on the staff of the infirmary, and *vice versâ*, to bring about a better understanding. In his opinion this was the moment for arriving at that understanding, and he hoped that those holding positions in the profession which would enable them to carry through such a reorganisation would approach the problem with the single object of the advancement of medical education in Newcastle.

Sept. 15th.

SCOTLAND.

(FROM OUR OWN CORRESPONDENTS.)

The Edinburgh and Leith Medical Practitioners' Association.

THIS association of registered medical practitioners residing in Edinburgh, Leith, and district has been founded with the object of promoting the interests of the medical profession by serving as a medium of friendly communication between members. The annual subscription is for the present fixed at the low sum of 5*s*. There will be an inaugural dinner on Oct. 16th, on which date the first general meeting will be held, when a debate of special interest to general practitioners will be arranged. The following have accepted office in the new association, which promises to be a practical success:—Honorary Presidents: Dr. J. O. Affleck, Dr. Joseph Bell, Dr. T. S. Clouston, Sir Henry Littlejohn, and Sir A. R. Simpson. President: Dr. William Nicol Elder. Vice-Presidents: Dr. T. Monck Burn-Murdoch, Dr. James Carmichael, Dr. Alexander James, Dr. James Ritchie, and Dr. T. R. Ronaldson. Honorary treasurer: Dr. H. Martyn-Clark. Honorary secretaries: Dr. John M. Bowie (46, Grange-road, Edinburgh) and Dr. John Orr. These officers will be assisted by a large committee representing different localities.

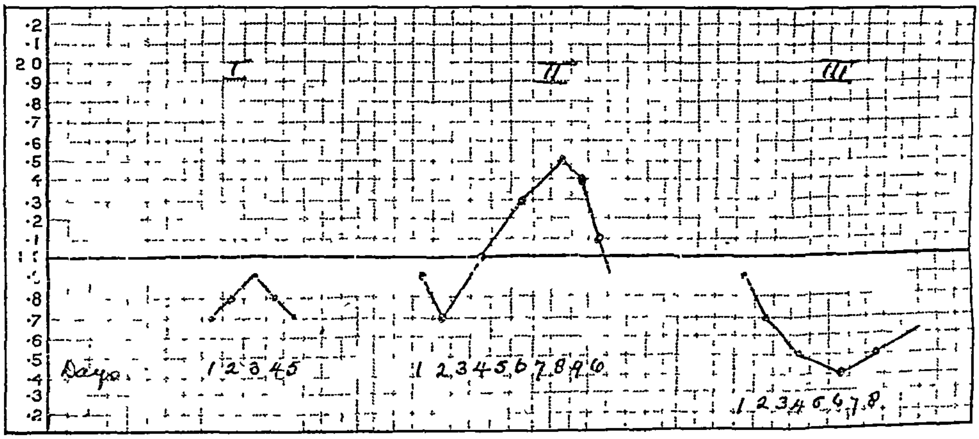
Sanitary Congress at Peebles.

The Sanitary Association of Scotland last week held its annual congress at Peebles. Various subjects were discussed, the most important being the Milk-supply of the Country, with Special Reference to Prospective Legislation. This discussion was introduced by Dr. G. Matheson Cullen, convener of the public health committee, Edinburgh, who treated the subject from the point of view of the local authority in a burgh, while Dr. A. Campbell Munro, medical officer of Renfrewshire, gave the county local authority's view, its turn followed by a fall towards normal; or (3) a fall tending to be more or less permanent according as to whether the dose be small, medium, or excessive. These effects are diagrammatically represented in the appended charts.

The rise in the first case will, though quick, be short lived. In the second case the rise subsequent to the initial fall, or negative phase, will be more prolonged, and having reached its maximum will gradually fall towards the level it was at previous to inoculation. In the third case the fall may be so severe as to last a considerable time, in some cases even never regaining its previous level without a further inoculation of minimal doses of vaccine. All gradations between will occur according to the dose of vaccine, and these varying results are designedly aimed at, according to the nature of the case in hand. There is thus no ideal opsonic curve in general to be aimed at, though in a particular case one particular form of curve may be ideal.

The fall subsequent to inoculation is called by Wright the negative phase, the subsequent rise he calls the flow, and the gradual fall towards normal he calls the ebb, the tides of flow and ebb together constituting the positive phase. In addition a phenomenon has been noted, occurring mainly in auto-inoculations produced by passive congestion and similar measures called the false rise. Here a slight rise precedes the negative phase but it is of small importance. question of dosage. In the case of (1) this in certain conditions would be an ideal curve in the circumstances. Taking, for example, a case of septicæmia, with or without a localised focus, it would be disastrous to induce a negative phase of any duration at all. During a negative phase of only a few hours' duration all the symptoms might be profoundly aggravated, the toxæmia deepened, the temperature raised, and pain, if present, increased, and it is probable that owing to the low protective power on the part of the blood foci of suppuration would be initiated in many hitherto uninfected areas. Obviously in such cases the aim of the immunisator should be to produce a maximum rise in protective substances compatible with an entire absence of negative phase. Nor even if no negative phase be produced should the dose be large enough to delay the elaboration of protective substances. If the dose be of such a size that the above desideratum be fulfilled the temperature should fall, pain and discharge should decrease, and a diminution of any local congestion and swelling that might be present should be noted, and these symptoms would in most cases be sufficiently marked to enable a determination as to re-inoculation to be made. Such cases as the above will usually be comprised in the following—erysipelas, cellulitis, lymphangitis, and puerperal fevers and septicæmias generally, in which, even if the process be more or less localised, a temporary lowering of resistance may be answerable for an alarming increase in the area of the process.

FIG. 1.



Diagramatic opsonic charts of the effects achieved by varying doses of vaccine. Referred to in the text as Diagrams (1), (2), and (3).

In general in the treatment of infections it is desirable to maintain an average high level of resistance. Thus, in the case of an effect such as Diagram 1 re-inoculation would be necessary very shortly; in Diagram 2 a second inoculation would be indicated, as the curve was falling to normal; whereas a minimal dose of vaccine might be advisable in Diagram 3 when the fall had ceased to bring the resistance back to the initial position.

Within limits it may be said that the duration of the effects produced by any one inoculation varies proportionately to the dose of vaccine inoculated—that is to say, that the longer the negative phase the longer the positive phase will be. However, a point is soon reached beyond which the duration of the negative phase is only increased at the expense of the positive phase, and ultimately no positive phase accrues at all, as indicated in Diagram 3. Here it may be stated that no attempt is made, except in cases of very low resistance initially, to superpose one positive phase upon another without any intervening negative phase. In general, an effect similar to that depicted in Diagram 2 is aimed at, constantly repeated, so that the sum total of the individual effects of a series of inoculations shall result in longer average duration of time of increased immunity and shorter average duration of time of decreased immunity as compared with that of a normal individual.

Before leaving the consideration of the three classes of curves produced by varying doses of vaccine it may be advisable to correlate with the opsonic results certain clinical symptoms and at the same time consider generally the

Thus it follows that in any infection which is not strictly localised, and more especially in septicæmias, the curve to be aimed at is one in which no negative phase occurs. In other words, the dose must be minimal in size. The corollary is that the response invoked is short, and therefore reinoculation must quickly follow, even to daily doses. In such cases the opsonic index is of paramount value as a guide, but as indicated above much assistance as to dosage and interspacing may be gained by the general symptoms and local signs.

Apart, however, from such severe cases as have been taken into consideration above, where a temporary lowering of the resistance is absolutely disastrous, it is inadvisable to give such a dose as to cause a negative phase in many chronic local conditions of less severity. To illustrate my meaning I will instance such a case as that of chronic tuberculous lymphatic glands. Such a case might well, and does mostly, show a constant low resisting power, as indicated by several successive tuberculo-opsonic indices of between 0·70 and 0·80. In such a case it would be desirable to aim in the first instance at such a curve as that in Diagram 1, so that a resistance equal to normal might be achieved without any intervening negative phase. A normal index having been thus attained either by one or two minimal doses of tuberculin, larger doses might then be given; an effect being aimed at such as depicted in Diagram 2, which will shortly come under consideration.

In considering those cases in which it is desirable to aim at producing the effect depicted in Diagram 2 we encounter

The Public Health of Cork.

The annual report of the medical superintendent officer of health in Cork suggests that the efforts of the guardians of the public health to procure a food-supply for the people are not always adequately supported by the magistrates. During the year 7012½ pounds of beef, 2819½ pounds of pork, 59 pounds of veal, 403½ pounds of mutton, 3535½ pounds of fish, 77 pounds of fruit, 95 pounds of fowl, and 116 pounds of onions were seized and destroyed as unfit for human food. Arising out of these seizures there were 18 prosecutions, but the penalties aggregated only £3 5*s.* 6*d*. This report also shows the distressful prominence of the tenement question in Cork as well as in Dublin. Of the 12,480 houses in the city of Cork 1500 are of the tenement class, and these abodes shelter 23,000 persons—nearly one-third of the whole population. The medical officer of health states that many of these dwellings are old and decayed and unfit for human habitation. In the same connexion, too, the report states that: "There can be no doubt that overcrowding exists in Cork to a very large extent, consequent on insufficient house accommodation for the poorer classes, where the density of the population is about 33·6 persons to each acre." This is one of the very many cases in which a boon would be conferred on the community by the passing into law of the Housing Bill.

Tipperary and the Tuberculosis Bill.

At a meeting of the South Tipperary county council last week Mr. John Cullinan, M.P., drew attention to the fact that "the Bill provided for the building of sanatoria, appointment of doctors, nurses, veterinary surgeons, &c., the expense of all which was to come out of the pockets of Irish ratepayers. It was an Imperial question and one that could not be dealt with except out of Imperial funds." The chairman (Mr. J. F. O'Ryan) agreed that it could not be adequately handled except by Imperial funds, and after some discussion a resolution was passed declaring that, while approving of any practical steps which could be taken to provide against or check the spread of tuberculosis, which they considered a national calamity brought about by the want of proper attention by successive Governments to the needs of the poor people, the council protested most emphatically against the financial provisions of the Tuberculosis Bill now before Parliament, which would place the entire expense of sanatoriums, &c., on already overburdened ratepayers, and the council claimed that it was the duty of the Treasury to finance any scheme dealing with the spread of the disease.

Sept. 15th.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

Ritual Circumcision and Medical Men.

THE recent Separation Law which divorced religion from the State in France and which has abolished the stipends paid by the Government to the ministers of various religions has been fraught with a number of unexpected results, one of which concerns the medical profession. It is common knowledge that amongst the Jews circumcision is practised by a special official called a *mohel*. Under the old *régime* the State recognised this special case in consideration of the ritual aspect of the operation, and by a relaxation of the French law forbidding the performance of operations by unqualified persons it was laid down that circumcisions performed by a non-medical *mohel* should be permitted without being considered to constitute illegal medical practice. But since the new law under which the State takes no official cognisance of the existence of any religion or of any religious ceremonial in France the *mohelim* have come to be regarded as illegal practitioners who perform operations without the title of doctor of medicine and who consequently lay themselves open to prosecution. The Jewish authorities are quite content to agree henceforward only to employ doctors of medicine as *mohelim*, as is the almost universal custom in well-to-do families. But they desire not to oust from their occupation the old *mohelim* who were recognised before the present law. It is now proposed that these men should still be allowed to circumcise until they have all dropped out, conditional upon the presence of a doctor of medicine at the operation and at subsequent dressings.

The New Edition of the Codex.

The *Codex Medicamentarius* is the French Pharmacopœia and the possession of a copy of it is obligatory upon all French pharmacists. They are obliged to keep in stock all the drugs in the official list. The book further gives the composition and official methods of preparation of all such drugs and compounds and includes a discretionary list of such new remedies as have been proved of service. As therapeutics is a progressive science, from time to time the Codex is revised completely and a fresh edition is published under the direction of a special commission which advises the Minister. The original Codex appeared in 1818, the second edition in 1837, the third in 1867, the fourth in 1884, and the fifth in July last, 24 years after the preceding issue. It shows a large number of alterations which are chiefly directed to the simplification of many preparations, such as the tinctures of iron and opium, in the manner recommended by the recent International Convention that considered the maximum doses of potent drugs. A crowd of old preparations which have fallen into disuse and which had become stereotyped in former editions have been swept away in this one. On the other hand, a certain number of new drugs are included, amongst which are adrenalin, theobromine, tuberculin, and other agents employed in opsonic, vaccine, and serum therapy.

Gynæcological Operations in the Treatment of Neuroses.

At the Eighteenth Congress of French Alienists and Neurologists which met at Dijon from August 3rd to 10th this question was discussed. M. Schuyder began by *maintaining* that gynæcological affections do not cause psycho-neuroses but that in certain cases the functions of the female pelvic organs, whether there be any structural change or not, by reason of the nervous instability of the patient, may be accompanied by subjective symptoms giving rise to irrational ideas which end in hypochondria. In such cases the failure of rational psychotherapy is sufficient justification for surgical interference.

A Monument to Professor Cornil.

The compatriots and friends of the late Professor Cornil, whose career I laid before your readers at the time of his death last spring, have recently appointed a committee for erecting a monument to his memory at Cusset, his birthplace, a town not far from Vichy in the department of the Allier. A public subscription list has been opened under the auspices of the committee, which includes the President of the Republic, a former president, M. Loubet, the Dean of the Faculty of Medicine, and numerous professors and medical men.

Medical Attendance at the Paris Theatres.

The prefect of police has just issued a new order dealing with theatres, cafés, concert-rooms, and other public places of amusement. After some new regulations dealing with the question of first aid, lighting, and sanitary matters, he modifies the old regulations by which it was obligatory upon all places of entertainment having a seating accommodation of over 800 to *provide the services* of a medical man. Moreover, the medical man is no longer obliged to be at the theatre as formerly for a quarter of an hour before and for the same time after any performance.

The Adulteration of Foodstuffs.

The Inspection Department of the town of Paris has, during the second quarter of 1908, dealt with 3015 samples, which have led to 1148 prosecutions. Of this number analysis established the fact of adulteration in 48 per cent. of the samples of milk officially taken, in 31 per cent. of the samples of wine, and in 26 per cent. of the samples of other foodstuffs, being 35 per cent. of the total number of samples officially taken. These do not include samples taken for the purpose of control or at the instance of a judge (*commissions rogatoires*).

Sept. 14th.

ITALY.

(FROM OUR OWN CORRESPONDENT.)

Hydrophobia.

FOR Italian physicians this is indeed a formidable accompaniment of the hot season when the *rabies canina* is prevalent enough to give it a double right to the name of scope of this article to do more than just indicate the procedure to be adopted.

As pointed out by Dr. John Freeman, the phenomenon of auto-inoculation is often observable where a circumscribed local infection is subjected to such treatment as to cause a temporary increase of circulation through the part. Such increased blood-flow may act in one of two ways, or in both ways at once. It may carry into the general circulation a greater or less amount of the products of the microbe, or of the microbe itself. If this be not excessive results comparable to those observed after an ordinary inoculation of bacterial vaccine occur; that is to say, a short negative phase followed by a positive phase and subsequent fall towards the pre-existing condition will occur and may be demonstrated if the opsonic indices to the organism in question be measured. Secondly, such increase of local circulation may cause an increased outflow of lymph, whereby a greater quantity of protective substances are carried into the infected areas and healing tends to result.

The phenomenon of auto-inoculation may be made use of for the purpose of diagnosis. An obscure joint swelling may be so treated as to cause an increase of the local circulation when, if tubercle be present, a variation in the tuberculo-opsonic index will occur, or if gonococcus be the cause a variation will occur in the opsonic index to the gonococcus. An enlarged lymphatic gland may be carefully massaged and the blood examined before and after massage. If a variation of wide dimensions in the tuberculo-opsonic index occur tubercle is the cause of the swelling, or at least is present as a secondary infection. A variation to be diagnostic should extend over a distance at least equal to three-tenths of unity, unity being taken as the opsonic index of the normal healthy person. Thus a variation from 0·8 to 1·10 would be considered strong presumptive evidence of infection. The presumption is the greater if a number of opsonic indices when plotted out as a curve produce a curve without irregularities. Again, a high opsonic index is at all times more suggestive of infection than one below normal. It is to be pointed out that general and indiscriminate massage of infected joints or lymphatic glands is not advocated, each case being weighed on its own merits. At St. Mary's Hospital we constantly use Bier's method of passive congestion as a means of producing a diagnostic auto-inoculation. Cautious exercise of a previously immobile joint often gives valuable indications as to the nature and activity or otherwise of any infection, if opsonic indices before and after movement be taken.

The fringe only of the question of bacterial diagnosis is touched in the above remarks. The elucidation of any particular case must be left to the clinical observation of the practitioner, aided by such bacteriological technique as he may have at his command. Obscure infections must perforce be left to the bacteriologist and preferably one conversant with the technique of opsonic estimations. Such a question, for instance, as the diagnosis between tubercle and gonococcus may in some obscure cases baffle even an experienced bacteriologist, if he be not also an opsonist.

2. We now come to the consideration of the second subheading—viz., *the estimation of the amount constituting a correct dose and the period that should elapse before re-inoculation.* While on the whole general principles only will be enunciated a few examples will be quoted, and for the sake of simplicity the cases to be considered will be divided into two main classes—viz.: (*a*) Those cases in which the exhibition of a correct dose of an appropriate vaccine will be followed by recognisable and obvious clinical signs without any delay. An example of this class of case is afforded by a furuncle and, indeed, staphylococcal lesions generally. (*b*) Those cases in which a dose of vaccine, be it ever so appropriate, is not followed immediately by recognisable and obvious clinical signs or, it may be, any sign whatever. An example of this class of case is often afforded by a tuberculous lymphatic gland in which even objective symptoms may often be absent even when the dosage is appropriate.

Now it follows that the treatment of these two classes of case must be approached from a totally different standpoint. In the first class, where obvious clinical signs may be expected to follow a dose of vaccine, it is possible to determine within a few days whether our dose has been appropriate or otherwise. Taking for example an incipient furuncle, we will follow out a typical case. A patient with a history of recurrent furunculosis presents himself with a commencing boil and with a view to aborting it one gives him 50 million staphylococci and gives directions that he attend again in four days. On his second attendance one of three indications may be present: he may be better, he may be *in statu quo ante*, or he may be worse. In case the furuncle was seen early enough he is likely to be better or *in statu quo*. If he be better one has evidence that the dose of vaccine was large enough to cause an elaboration of a sufficiency of protective substance to go towards an abortion of the lesion; a similar or slightly larger dose of vaccine would be indicated. Again, if there has been little or no change the indications are that though a rise in protective substances may have occurred in the circulating blood, it is either not high enough or the blood, though maybe rich in protective substances, is not having free access to the congested area comprised by the boil. A larger dose of vaccine is indicated and some measure designed to determine the blood to the part. Such a measure, for instance, is a series of fomentations. It is likely that these measures will result in the absorption of the congested fluids and a return to the normal condition on the part of the area of the boil. There will in that case be no further evidence immediately observable as to the accuracy of any dose, but to insure a more or less permanent immunity gradually increasing doses are indicated until a maximum of 400 or 500 millions be reached, and the doses may be given at first weekly and later at increasing intervals. On the other hand, should a furuncle be under consideration that is clearly about to suppurate, a larger dose, say 500 millions, may be immediately given. The resistance will be depressed temporarily and the boil will quickly ripen and discharge with or without incision as may seem best. A week after the first inoculation a small dose of 100 millions should be administered and doses rising by 50 millions or 100 millions a time should be given at first weekly and later at increasing periods until a maximum of 400 or 500 millions be reached.

Another example of a lesion that gives early evidence as to the appropriateness of the dose of vaccine is afforded by a case of suppurating acne. Here an appropriate dose is followed by a temporary exacerbation of the signs lasting for 24 hours, after which amelioration occurs. If the dose be too small an immediate amelioration is observed; such an amelioration, however, is but short-lived; should, on the other hand, the dose be excessive and a more or less profound negative phase be produced, the lesions get worse for several days and only slowly get back to the condition they were in at the period of inoculation. In some cases of acne, especially in females, large doses of staphylococci are ill borne at first, and it may be some months before a dose of 400 millions will be borne without a marked negative phase ensuing.

Many cases of chronic eczema are associated with a low resistance to staphylococcus together with an abnormal fluidity of the blood. Small doses, gradually increased, of staphylococci combined with the internal administration of lime, preferably calcium lactate, may be given, such procedure in most cases producing an immediate and marked effect. A case came under observation with a history of nearly 40 years' duration. Half a dozen doses of 250 million staphylococci at fortnightly intervals, together with the administration of half-drachm doses of calcium lactate every other day for three doses, with a weekly rest between each series of three doses, cleared up the case in three months. A slight relapse six months after was cleared up with two more doses of staphylococci and some more calcium lactate, and for 18 months there has been no recurrence.

The examples quoted above are of typical cases, but occasionally cases are met with in which the dose has to be extremely small, and where any dose is followed by a negative phase lasting more than a day or 36 hours, it may be concluded that the dose was too large, and a smaller one must be given on the next occasion. A case of furunculosis of some years' standing came under treatment, and it not being at first realised that the patient was peculiarly intolerant of the ordinary doses, the dose was rapidly raised, and it was not until on two separate occasions that serious negative phases, followed by crops of furuncles, were caused by doses of 250 millions that it became obvious that an intolerance existed. A complete cure followed, when a series of doses of 50 million staphylococci were given, a cure that serve a term of at least three weeks every other year for six years. The students of the clinics, on the other hand, will have to serve a term of 19 days in this ward in groups of from six to eight, whilst graduates will also be enabled to profit by the new arrangement. The ambulance corps and the police have received instructions to send accident cases happening within a certain radius to this ward. Thus the clinic will offer abundant accident material for teaching purposes. Of late years there has been constant complaint that the clinics were lacking in material of such kind, and this condition of affairs seriously interfered with the teaching side of the clinics. In 1902 only 24 cases of cerebral concussion, 76 cases of bullet wounds, 18 stab wounds, and 12 cases of extensive burns were taken to the clinical wards, whilst the majority of accidental injuries were distributed amongst the suburban hospitals and thus lost for teaching purposes. The addition of about 60 beds (the remainder of 40 must be kept for military purposes and accidents requiring internal treatment only) will not only relieve pressure, but will also do away with the difficulty in teaching an important part of surgery. The new arrangement may be modified a little in some points but its adoption is already sure.

What Constitutes a Specialist?

The question of bestowing the title of *Specialarzt* (specialist) for a certain branch of medical art upon a duly qualified man has again been brought to the front by the Vienna Medical Council, which asked the medical councils of the other Austrian districts for their opinion on this subject. Four years ago a similar movement sprang up but it did not gain much publicity. At present the increase of specialists seriously handicaps the general practitioner. Some men style themselves specialists in gynæcology and diseases of children, thus taking away from the all-round man a large portion of his practice, without ever having had any hospital practice. On the other side, actual specialisation has so far progressed in our country that in Vienna there are, amongst 3000 practitioners, no fewer than 800 specialists; of these 280 are either professors or *privat-docenten*. Suggestions have therefore been made to stop for the future the wholesale increase of specialists of the self-styled type. A special study of at least three years, either under a specialist of recognised reputation or in the special ward of a hospital or a polyclinic, will be indispensable. A number of original scientific publications will be required, besides giving proof of actual work in the chosen branch. Furthermore, a medical man will not be recognised as a specialist in more than one branch of medicine, except, of course, in such subjects as may be considered in connexion, for instance, ear, nose, and throat; or skin and sexual disease.

A Case of Early Ossification of the Coronary Suture of the Head.

Dr. Algyogyi at a recent meeting of the Medical Society of Vienna showed a boy, aged 15 years, subject to epileptic seizures. The history of the patient was not unusual except that his mother mentioned that she noticed an abnormal configuration of the boy's head at the time of his birth. The head was very high, the fronto-occipital diameter, as well as the bi-temporal one, being very small compared with the mentoparietal diameter. Since the age of ten years the boy noticed cramps of the adductory type in his fingers of both hands; a few months ago he suddenly had an epileptic seizure lasting five minutes and since then such fits have occurred repeatedly. The examination of the patient showed besides the abnormal shape of the head the presence of asymmetric development of the skull, the right side being less developed. The teeth were of the Hutchinson type; there was marked exophthalmos of the left eye, without nystagmus. An x ray photograph revealed a shortening and narrowing of the anterior cerebral fossa, an increased convexity of the middle fossa, and very marked "impressiones digitatæ," proving the existence of increased intra-cerebral pressure in combination with many rough spots on the inner aspect of the skull. Cases of this early ossification of the sutures of the skull have *only* been recorded comparatively lately. Sometimes the ossification takes place before birth, sometimes much later. The etiology of the abnormal ossification is not yet clear. Some writers consider syphilis or rachitis responsible for it, others point to meningitis or pachymeningitis, whilst a great many other authors believe that an intra-uterine meningitis with subsequent chronic hydrocephalus accounts for the condition. In several cases trephining of the skull was followed by improvement of the symptoms; this pressure-lowering operation is also contemplated for the patient mentioned above.

The New Clinics in Vienna.

The erection of three new clinics, in addition to the two gynæcological pavilions already finished, has been begun. The clinics will comprise von Noorden's internal clinic, a laryngological ward, and a children's ward. Von Noorden's clinic will have 100 beds, with an isolation pavilion, clinical teaching halls, a lecture hall seating 236 students, a special dietetic kitchen, and laboratories for experiments on metabolism. The Chiari clinic for diseases of the nose and throat will have 48 beds with a pavilion for seven diphtheria cases; and the third clinic, under Professor von Escherich, will have 44 beds for children, a pavilion for 10 infants, and a station for 12 "boxes" or "couveuses" for premature infants. The infection wards consist of a pavilion with 21 diphtheria beds and another pavilion with 24 scarlet fever beds. The lecture hall of this clinic will hold 200 students, against 100 seats in the Chiari lecture hall. A good operating theatre will be attached to both the latter clinics. The exterior of the building will be finished in 1909, whilst the completion of the interior has been fixed for the summer of 1910; the cost of the erection, together with all apparatus and fixtures, has been estimated at £200,000. The plans are in accordance with the desires of the professors, and all the latest innovations and the best material, together with the best recognised equipment, have been allowed for by the committee. The fittings will cost about £60,000. Care has been taken to provide for sufficient rooms for students to spend at least twice a year a term of a fortnight as junior assistants, so as to come in close contact with patients and diseases. Hitherto this most important part of a medical curriculum was rather badly handicapped by sheer want of accommodation.

Sept. 12th.

NOTES FROM INDIA.

(FROM OUR OWN CORRESPONDENTS.)

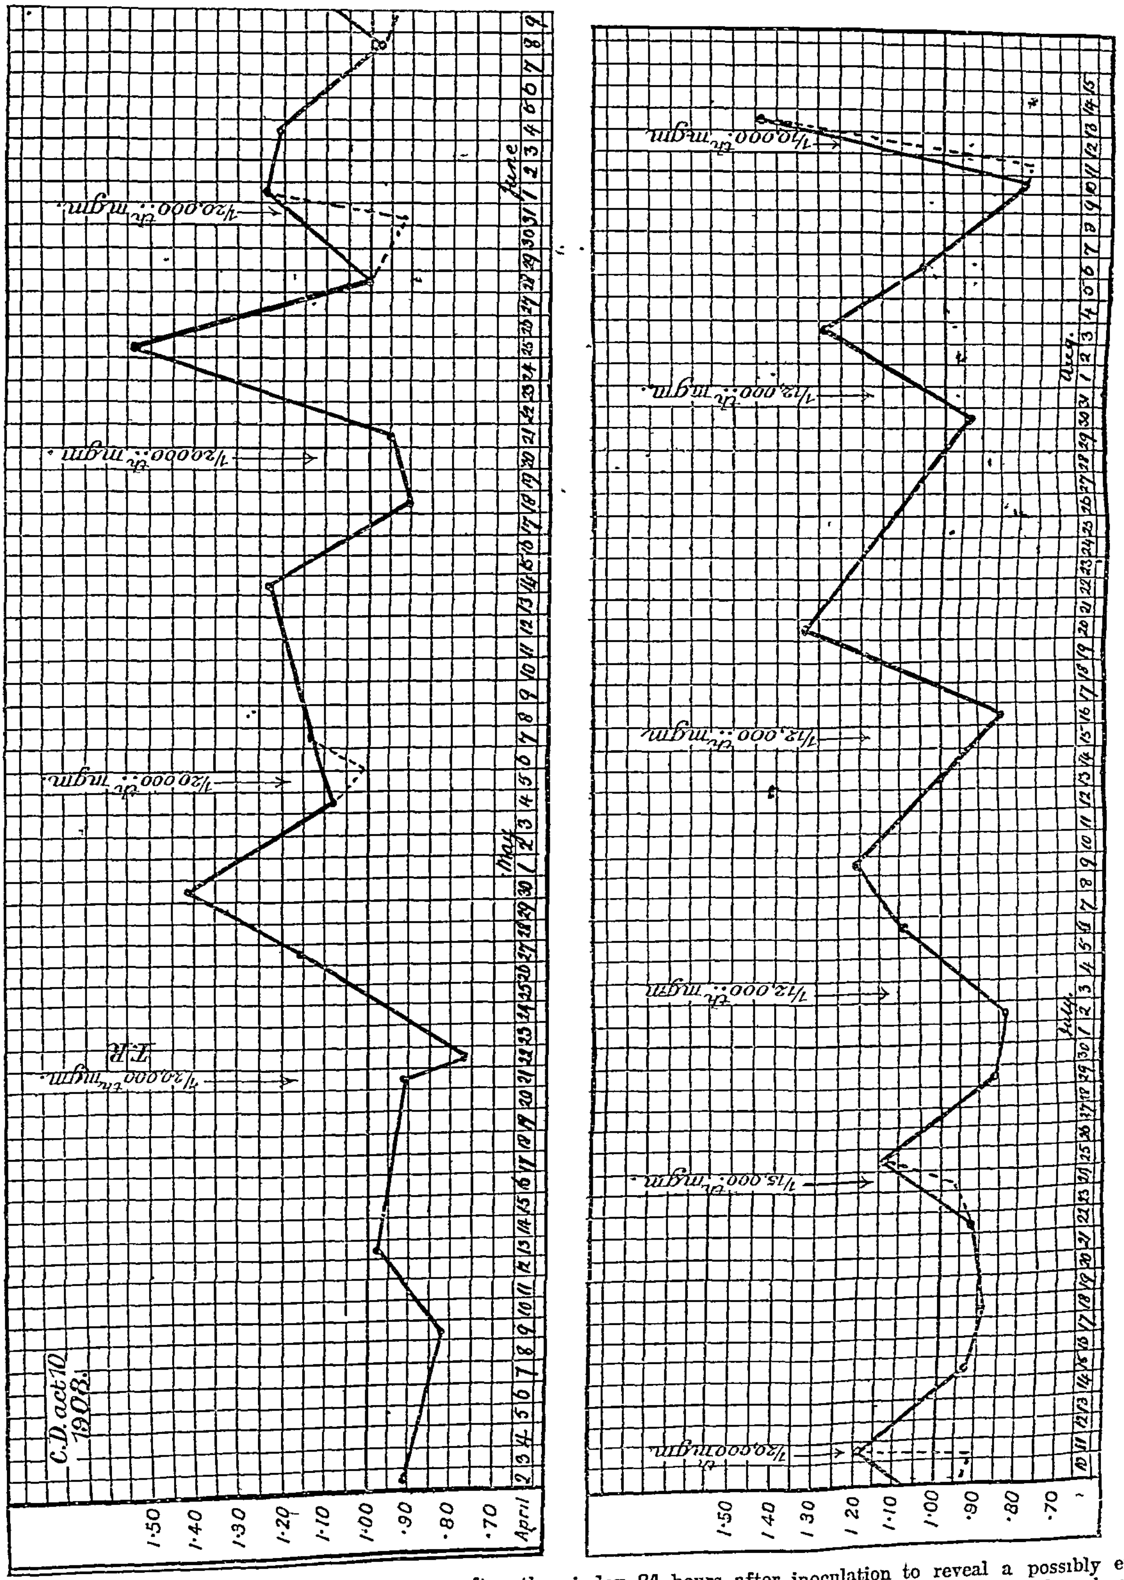
Military X Ray Equipment in India.

IN 1904 Sir Thomas Gallwey, K.C.M.G., C.B., principal medical officer His Majesty's forces in India, submitted a carefully drawn up scheme for the consideration of the Government of India which comprised the provision of 15 complete sets of x ray equipment for India for use in peace and war. The apparatus selected consisted of portable outfits for use on field service. One complete set was obtained from London at once and subjected to severe and prolonged tests on field service conditions, consisting of marching it loaded on mules for long distances over rough bridle paths, both in the plains and the hills, and, finally, by conveying the complete component parts from Dehra Dun to Simla, a distance of about 100 miles, over mountainous ranges by very rough tracks. On arrival at Simla in November, 1904, the entire apparatus was set up for a working trial and was inspected by a representative gathering at army headquarters, and while in working order it was reported on by a committee of medical officers consisting of Major H. W. H. Elliott, D.S.O., I.M.S., Captain E. Blake Knox, R.A.M.C., and Captain A. E. Walter, I.M.S. This committee expressed its opinion that the outfit was suitable in every way for use in peace and war. Lord Kitchener concurred in the finding of this committee and considered that the portable outfit should be used with general hospitals and hospital ships as well as with peace charges in order to accustom medical officers to its use in peace time and to avoid duplication of equipment. Another advantage of the portable apparatus was that it could be sent when necessary to out-stations away from the railway in which circumstances portability would be a great desideratum. The next step was the formation of a headquarters x ray institute at Dehra Dun, and Captain Walter was appointed superintendent and was given a suitable staff. This institute, besides carrying out x ray work for the civil Government and also for the military, became a training school for medical officers and subordinates (assistant surgeons and hospital assistants) for all branches of the medical services in India. It also undertook special forms of

From this it will be seen how small a dose was given in the first instance and how gradually it was increased. That from a low average resistance a high average resistance was attained and maintained. That the average period above the normal line was much greater after the course of inoculations was started than the average period below the normal line.

This particular case is instanced because a generous number of opsonic indices was estimated and it affords a better example of chart than when only two estimations between each inoculation are undertaken, which latter number is usual in an average straightforward case. The indications in such a case being to estimate the opsonic index 24 hours after inoculation to reveal a possibly excessive negative phase and on the seventh day or thereabouts to reveal the persistence or otherwise of the positive phase. If a high state of resistance be revealed inoculation is, of course, delayed for a few days.

FIG. 2.



An opsonic chart showing the responses to increasing doses of tuberculin.

an ophthalmic surgeon. He enjoyed the confidence of his professional brethren and his opinion was frequently in requisition as a consultant, not only in Newcastle but also in the northern counties of England. When in the zenith of his reputation he was invited to allow himself to be associated with the Newcastle Infirmary on the surgical staff, he respectfully declined the honour and gave as his reason that his time was so fully occupied that he would not be able to do justice to the appointment and had no desire to be simply an ornamental official. He was a courteous and Christian gentleman, the trusted friend and medical adviser of many families for more than half a century, and distinguished for his consideration, attention, and prudence."

JOHN WILLIAM BILLING STEGGALL, M.R.C.S. ENG., L.S.A.

Mr. J. W. B. Steggall, whose somewhat unexpected death took place on August 14th, at the house to which he took his young bride in 1854 and in which he had resided continuously ever since, was the eldest son of the late John Steggall, M.D. He was born in 1827 and in the year 1843 commenced his professional studies at Charing Cross Hospital. He passed through the course with distinction, receiving the gold medal of the Society of Apothecaries and qualifying as L.S.A. in 1848 and M.R.C.S. Eng. in 1849. He then held the appointment of house surgeon at Charing Cross Hospital for over three years, the duration of these posts not being limited 60 years ago as they are now, after which he was assistant to his father for some time, both in his *more strictly professional* practice and in the tuition which, in accordance with the custom of the day, was often given by physicians to students who in some cases resided, as well as studied, at a medical man's house. In this manner the late Mr. Steggall had, amongst other well-known pupils, Albert Smith under his charge, and the humorous sketches that appeared in the early pages of *Punch* under the heading of "The Medical Student" owed much to the writer's experience as a medical pupil in Dr. Steggall's house. Some of the names attached to the anecdotes were, indeed, but thinly disguised; those in the secret, however, admitted the accuracy of the sketches.

Mr. Steggall later carried on a large practice in Bloomsbury, though the modern changes in the residential character of the neighbourhood materially affected it. He never actually retired from practice, and even on the day of his death some old patients sent to ask his attendance or advice, but alterations in all the conditions of medical practice were bound to affect him, as they do all senior practitioners. In his profession he was inclined to be conservative, but his powers of diagnosis were admittedly high and his skill in dealing with such surgical work as falls to the lot of a general practitioner was undoubtedly great. His rather old-fashioned manner and his constant urbanity, together with the interest that an admirably trained and exact memory lent to his conversation, were valued by a large circle of friends.

Mr. Steggall was famous for his love for London. He did not sleep away from his house more than, on the average, once a year during his long occupation of it. One of his chief delights was to walk through the London streets, studying their new and old architectural features, or examining the books and engravings at the well-known dealers. His knowledge of architecture was extraordinarily minute and he was generally much better informed as to the principal English and continental buildings which he had never seen than those who had had the advantage of visiting the cathedral cities or the great centres of European history. His collection of engravings and drawings was large and detailed, and included many architectural designs from his own hand. His appreciation of this particular branch of art was very keen, and his criticisms were always marked by excellent taste. In addition to his knowledge of architecture and engraving he was learned in general classical and late Latin literature, and possessed a wide knowledge of Roman numismatics. His wife died in 1893, but of his family, numbering 12, the ten who survived their infancy are still alive. The eldest son is one of the two professors of mathematics at the University of St. Andrews, and the seventh son has followed his father's footsteps, having taken the medical course at Charing Cross Hospital and qualified as M.R.C.S. Eng., L.R.C.P. Lond. His second daughter was his constant companion for the last 13 years.

JOHN CAMERON, M.D., C.M. EDIN.

WE regret to record the death of Dr. John Cameron, medical superintendent of the Argyll and Bute Asylum at Lochgilphead, which occurred on Sept. 5th at Edinburgh, whither he had retired three months ago with a serious disease which gave no hope of his recovery. He was born at Killin 67 years ago and was educated at Edinburgh University, where he took his M.B., C.M. in 1872 and proceeded to the Doctorate five years later. Subsequently to his qualification he became a house surgeon at Glasgow Royal Infirmary and then assistant to the professor of the practice of medicine in his own university and assistant physician at the Edinburgh Royal Infirmary. He relinquished a career in internal medicine which promised so well to take a medical officership in the Crichton Royal Institution, Dumfries, and in 1874 succeeded to the superintendentship which he held until his death. He was a keen officer of the Argyll and Bute Artillery (Volunteers) and after some 15 years' service retired with the rank of lieutenant-colonel.

JAMES BRIERLEY HUGHES, M.R.C.S. ENG., L.S.A.

GREAT regret has been felt at Macclesfield at the death of Mr. James Brierley Hughes who was an old practitioner and prominent citizen of that town. He was attacked with serious heart trouble in December last but made a great improvement until a serious relapse occurred in August which resulted in his death on August 25th, when he was in his sixty-fifth year. He was the son of the Rev. John Hughes, rector of St. Peter's, Congleton, and was apprenticed to Dr. Bulloch of Congleton after being educated at the Macclesfield Grammar School. He came up to St. Bartholomew's for his hospital training, obtaining his qualifications in 1866. In the following year he returned to Macclesfield, where he was appointed medical officer of the workhouse, district medical officer, and public vaccinator, all of which offices he held until his death. He was an active councillor of the borough for the last five years, being a member of the water, library, health, and other committees. He was a keen militiaman, having joined the 4th Battalion of the Cheshire Regiment (Macclesfield Militia) as surgeon-lieutenant in 1873 and held the rank of Surgeon-Lieutenant-Colonel at its disbandment last year. Mr. Hughes leaves a widow, who is the daughter of Mr. A. E. Sears of Blackheath, three sons, and one daughter. Two of his sons, Dr. J. B. Hughes and Mr. Guy Hughes, are in medical practice in Macclesfield. The funeral, which by his own request was very quiet, took place at Congleton on August 29th. We take the following appreciation of the deceased gentleman from a local contemporary. "Bluff and outspoken, and always uncompromising in his detestation of sham and mere empty parade, Dr. Hughes was not given to 'coddling' his patients, or anybody else with whom he came into contact, but he nevertheless earned their respect and complete confidence. He possessed an inexhaustible store of good humour and had qualities of heart which, though rarely displayed openly, will cause his death to come to many with the force of a personal loss."

FREDERICK JOHN MASON, M.R.C.S. ENG., L.M., L.S.A.

AN old and well-known surgeon of Lincoln, Mr. F. J. Mason, passed away on August 25th at his residence, 6, Sibthorp-street. He had reached the age of 71 years, of which 43 had been spent in practice in the city. He was the eldest son of the late Mr. John Mason of Wisbech and was educated at University College, London. He obtained his diplomas in 1858, subsequently settling in Lincoln. He had not enjoyed good health since he suffered from a paralytic seizure 14 years ago, but his end came somewhat suddenly after a few days' illness. In 1869 he married the second daughter of the late John Stevenson of Barton-on-Humber who survives him with one daughter. Mr. Mason was a keen and successful surgeon and gained a considerable local reputation by his skill in the treatment of fractures in which he had always been interested. He enjoyed a large private practice. The funeral took place at Canwick-road Cemetery, Lincoln, two days after his death, and the tributes included a beautiful was followed on the 12th by a sli[illegible] in the neck, and the temperature, [illegible] normal, rose a degree, otherwise there was no constitutional disturbance. On the 13th the inflammatory signs passed off and the temperature *fell* to normal. On the 15th the wounds were covered by a thin delicate skin. On the 17th this skin *was shed and the wounds* were once more open. On the 20th another injection of 1-5000 cubic centimetre of T.R. was given, the opsonic index being again 0·7. This injection *caused*, 12 hours later, inflammation in the wounds with distinct pain, which lasted for 24 hours. In four days the inflammation had subsided.

On June 1st a bluish-white line of epithelium began to appear round the wounds. On the 3rd 1-5000 cubic centimetre of T.R. was again injected and the same clinical phenomena followed as on the previous occasions. On the 10th the condition was as follows: The upper wound was closed by thin, young, healthy cicatrix; the second wound was partly closed and showing healthy margins; and the third or lowermost wound was still open but was surrounded by healthy edge and floored with pink, healthy granulation tissue. On the 15th 1-2500 centimetre of T. R. was injected, the opsonic index being at this date 0·89 (practically normal). On the 17th the two lower wounds were almost closed and three days later all were completely covered and the patient was now allowed to go out in warm weather. On the 25th 1-2500 cubic centimetre of T.R. was injected, the patient remaining in bed on the two following days. This procedure was followed after each injection till the termination of the treatment.

On July 2nd 1-2500 cubic centimetre of T.R. was injected, the opsonic index being now 0·98. The patient was feeling in splendid health. The wounds had remained quite closed and the cicatrices were beginning to contract. On the 13th 1-5000 cubic centimetre of T.R. was injected. The scars were white and anæmic in places. On the 24th 1-5000 cubic centimetre of T.R. was injected. The scars looked strong, tough, and white. An area about one-eighth of an inch in diameter in the centre of the lowermost scar had broken down. On the 29th this breach was diminished to half its previous size.

On August 19th 1-25000 cubic centimetre of T.R. was injected. On this date only an area of the size of a pin's head remained bare. On the 25th the wounds were entirely closed and the cicatrices appeared fine, white, and strong. There was wonderfully little marking. The patient has remained well ever since and started work on Sept. 3rd.

CASE 2.—A man, aged 26 years, came on May 20th, 1908, complaining of an inflamed chin of a week's duration which proved to be a case of folliculitis barbæ. The infection involved the whole of the hairy part of the face and extended down the front of the neck. The chin was greatly swollen with subcutaneous abscesses and was the seat of much tension and pain. In a smear taken from one of the pustules the dominant micro-organism seemed to be the staphylococcus pyogenes aureus. There were also present a few streptococci and other pyogenic bacteria. The hair-roots were examined, but no trichophyton spores could be detected. The diseased parts were treated by epilation and by the application of boric acid and starch poultices, followed by antiseptic lotions and ointments for six weeks, but there was little or no improvement. Some of the pus was now plated, incubated, the right colony selected, and by a succession of sub-cultures a pure emulsion of staphylococci was obtained. This we attempted to sterilise by exposing it for one hour to a temperature of 68° C., or 2° above that which is sometimes recommended, but a loopful incubated for 12 hours on agar showed growth. We therefore decided upon sterilising the emulsion at 100° C. for 40 minutes, the measured doses being again steamed for 20 minutes in the ampoules immediately before sealing. We argued that even if one loopful or more should prove sterile on incubation this was no proper guarantee that the rest of the emulsion was free from living bacteria, whereas one hour at 100° C. practically eliminated all risk. Some consider that this temperature materially alters the toxins, so making the vaccine less efficient, but the favourable results obtained in this case, with a possibly modified toxin, would make us hesitate to take any risks with bacteria which had only been subjected to the lower temperature.

On July 4th a dose of vaccine containing 45,000,000 staphylococci was injected. The opsonic index for this bacterium was then 1·10. Wright has recommended 500,000,000 as a suitable dose, but other observers have obtained *good* results from smaller *numbers*. The patient was kept in bed for two days after the injection and this course was *followed after* each subsequent inoculation. All local *antiseptic treatment* was stopped. On the 5th there was a severe inflammatory reaction, with pain, swelling, and redness at the site of the disease. On the 6th the reaction passed off and a day later some of the pustules began to disappear. No new pustules made their appearance on the chin, but *a crop came out on* the right flank. On the 8th 90,000,000 staphylococci were injected. Local reaction followed on the 9th and did not subside until the 11th. Succeeding this there was a period of *improvement*, many pustules disappearing, and a crop again occurred on the right flank, disappearing in the course of four days. On the 15th the opsonic index was 0·9 and an injection of 125,000,000 was followed by a sharp reaction and the appearance of a few pustules on the flank. On the 17th the reaction passed off, the pustules on the flank disappeared, and a period of improvement set in which continued steadily until the 24th, when the whole of the inflammatory process had subsided except at the point of the chin, where an area of about one square inch still exuded pus. On the 24th 200,000,000 staphylococci were injected and after the local reaction had passed off there was further improvement. All pain and tension had completely disappeared. On the 27th the process had become limited to two small pustules on the chin and a few scabs.

On August 5th 300,000,000 staphylococci were injected. No pustules were present on the chin on the 10th and the hair was growing luxuriantly. For the first time during the course of treatment no pustules on the flank followed this fourth and last injection. The patient has remained quite well up to the present time.

CASE 3.—A boy, aged ten years, was brought to us in the beginning of June, 1907, complaining of pain, stiffness, and swelling over the first metatarsal bone and proximal phalanx of the great toe of four months' duration. The case was one of tuberculous disease of the metatarso-phalangeal joint. Calmette's ophthalmic reaction was positive. The boy was put to bed, the foot was immobilised in a splint, and cod-liver oil and a nutritious diet were prescribed. The general condition was asthenic. In the course of a month the swelling had increased and showed signs of liquefaction. The question of an excision was considered, but it was decided to incise and evacuate. This was done at the beginning of August. Shortly after this the skin broke at two other place, and there were now three sinuses discharging. *Treatment* by Bier's method was initiated, the congestion being kept up for two hours twice daily. This had a distinctly *salutary* effect. The swelling began gradually to subside and the discharge lessened. One sinus closed completely, but the other two still remained open, discharging a little serum every day. During February, 1908, a second sinus closed, *but opened* again in a few days. This was repeated *on two or three* occasions during the next three months; *the third* wound never closed. The boy's general health had improved.

On June 13th, 1908, 1-10000 cubic centimetre *of* T.R. was injected and the patient was kept in bed the following day. There were a well-marked local reaction with *congestion* and increased discharge from the sinuses. *On the* 15th the reaction had subsided and during the following seven days there were a continued diminution of the *swelling and* a lessening of the discharge. *On July 2nd another* 1-10000 cubic centimetre of T R was injected. *After the reaction* had passed off further improvement occurred. *One of the* sinuses closed, while the other remained open, discharging a little serum every second or third day. At the beginning of August the remaining sinus closed, but opened up again about the middle of the month. *On the* 19th 1-10000 cubic centimetre of T.R. was *injected*. After the reaction had passed off *the remaining sinus* closed and remained so. On Sept. 1st the scars were white, soft, pliable, and depressed. Comparatively little thickening was present at the site of the lesion. *The joint remained stiff.* On this day an injection of 1-10000 cubic centimetre of T.R. was followed by a very slight reaction. The last closed sinus opened on the 2nd and emitted *a drop or* two of blood-stained serum. On the 3rd the dressing was absolutely dry, no *discharge being* present nor has there been *any reappearance of the discharge* since that date.

colds which, he thought, had a great future. Dr. Broadbent read a note on Homburg and Some Other Spas. He described the waters and baths which gave the best results with chronic dyspeptics. Compared with England the finer climate, better management, and consequent greater cheerfulness of foreign spas gave them a great advantage.

University College, Bristol.—The fête recently held at the Zoological Gardens, Clifton, for the purpose of raising funds to clear off the debt on the recreation ground of the University College Union was very successful. The gross receipts were £1993, and after paying expenses the sum of £896 will be handed to the University College Union.

Manchester Royal Infirmary.—In view of the closing of the old Manchester Royal Infirmary, which will take place shortly, it is proposed to hold a gathering of past and present residents who wish to visit the old building again. A dinner will be held on Thursday, Oct. 15th, and the old and new hospitals will be open for inspection on Oct. 15th and 16th. Any former resident officer or resident apprentice who has not received notice of the dinner is requested to communicate with the resident medical officer of the infirmary, who is acting as secretary for the gathering.

The Pirogoff Society and Political Propaganda.—The *Novoe Vremya* reports the arrest of D. B. Zhbanko, secretary to the Pirogoff Society, at whose residence 1500 pamphlets were found entitled, "What you must know to Combat Contagious Diseases." Only the first few pages were devoted to the subject of the title, the rest were filled with anti-Government propaganda. The executive offices and library of the Pirogoff Society were searched at the same time, where 600 of the pamphlets were found. The society's journals were removed.

Failure of the Champagne Vintage.—It is reported from the chief departments of the champagne country that the vintage of 1908 simply does not exist, so disastrous have been the ravages of mildew. This blow is the more unfortunate just now inasmuch as there is a bitter feeling amongst the growers in regard to the unchecked manufacture of wines purporting to be champagne but which is made from grapes grown outside the real champagne district. They ask for the same protection at the hands of the State as is accorded to the producers of Cognac brandy which is defined to be the product of the distillation of wines produced in the Charentes. It is feared that if a practice of substitution is continued there will be a general rising amongst those engaged in the champagne industry who realise that their livelihood is menaced.

The New Water Charges in London.—A movement is on foot in the City of London to ask the Lord Mayor to summon a meeting of ratepayers to protest at the Guildhall against the new charges of the *Metropolitan* Water Board. The Lord Mayor has expressed his willingness to preside at such a meeting if a sufficiently large requisition is presented to him, and during the next few weeks it is expected that a considerable number of prominent ratepayers will give the chief magistrate the mandate he seeks. The dissatisfaction aroused in the City by the new water rate is very great. It is understood that at the projected meeting a demand will be made for such an amendment of the Act of 1907 as will lessen the burden imposed upon City ratepayers, the adoption of supply by meter being suggested, no other means appearing feasible.

Tuberculosis in Norway.—The annual report of the sanatorium for tuberculous patients at Reknaes on the west coast of Norway shows that during the year ending Dec. 31st, 1907, there were 269 cases admitted and 265 discharged. The average period of residence was 88 days, the maximum being 151 days. Of the 269 cases admitted 28 per cent. were in the first, 50 per cent. in the second, and 22 per cent. in the third stage of the disease, while among the 265 cases discharged there were 80 in the first, 125 in the second, and 48 in the third stage. Of the 80 cases in the first stage and of the 125 cases in the second stage 54 per cent. and 10 per cent. respectively were discharged "recovered," while of the 48 cases in the third stage 58 per cent. were discharged improved. There were two deaths, one of which was due to nephritis with uræmia and the other to perforated duodenal ulcer with general peritonitis. Calmette's ophthalmic reaction and Pirquet's cutaneous reaction were tried in many instances. That these reactions may be of value in doubtful cases is highly probable, but owing to the great variability of the results sufficient data have not yet been collected to warrant publication. The average cost per diem for a patient was 1*s.* 11*d.* (kr. 1·70), of which 1*s.* 1¼*d.* (kr. 0·99) were spent on food. The average temperature for the year at Reknaes was 5·9°C., with a maximum of 24·3° and a minimum of –11·8°C.

Pontypridd and District Cottage Hospital.—Over £1500 have been already received towards the building fund of the proposed "Pontypridd and District Cottage Hospital."

The Vaccination Act in East Devon.—The question of the fees paid to public vaccinators has been engaging the attention of the boards of guardians in East Devon, and in some cases considerable reductions have been proposed. At Axminster recently the public vaccinators all resigned their appointments in consequence of the reduced fees which were offered. At the last meeting of the Honiton board of guardians a letter was read from the Local Government Board stating that the guardians must offer such fees as would attract qualified medical men for the positions. The guardians apparently realise that the local medical men are determined only to accept the scale of fees at present in force, and a member of the board gave notice that at the next meeting he would move that the guardians revert to the old conditions.

The Kepler Society.—A Kepler Society (Keplerbund) has been founded recently under the auspices of certain German men of science "to counteract the advances which Monism has made and which appear to be of an atheistic tendency." An appeal to the public has been made and the society has now about 3000 members. The object of the society is to instruct the lay public in scientific truths and to promote its interest in the study of nature entirely apart from religious views. About 140 men of science have offered their services as public lecturers and scientific contributors. Six popular treatises have already been issued. A committee of 29 members has charge of the organisation. Dr. Desmert, D.Ph., of Godesberg, is scientific director. Members pay an annual subscription of at least 5 marks.

The Health of South Devon in 1907: A Record Year.—Mr. W. Harvey has just presented to the Devon county council his summary of the reports of the medical officers of health of South Devon for 1907. The report deals with the rural and urban sanitary districts in South Devon and shows that the death-rate for the year was 14·3 per 1000. Pulmonary tuberculosis for the first time had caused less than 300 deaths—viz., 294. The death-rate of enteric fever was 0·05, the lowest on record. The infant mortality was 93 per 1000 births, the lowest recorded. 313 deaths were due to cancer; this is the first occasion on which the deaths from cancer exceeded those due to pulmonary tuberculosis. 945 cases of infectious disease were notified in 1907, compared with 1144 in 1906. The birth-rate for 1907 was 20·3, the lowest on record.

Third International Congress for the Care of the Insane.—This Congress will be held at Vienna from Oct. 7th to 11th, under the patronage of the Austrian Government and of a distinguished council. The proceedings will embrace all questions relating to the insane, not only of medical interest but also of legal, technical, administrative, and pædagogic interest, as will have been seen by a list of some who propose to take part which has already been published. The Congress aims at putting us in possession of complete information upon the present position of lunacy administration in the different countries; the care of the feeble-minded, the nursing of lunatics, the arrangements for their restraint, the care of the insane in armies, and all legislative aspects of these questions will be dealt with in different communications, after which a report will be read upon the proposal of Dr. Frank of Zürich to establish an international institute for the study, prevention, and treatment of mental diseases. Excursions to inspect noteworthy places will be made and in particular to the hospital for a condition known as eosinophilia in those who are infected, whether they show symptoms or not.

Method of infection of mine.—This is brought about by (1) the mine becoming infected by men who have brought disease home from countries where it is endemic (for example, soldiers from India, Egypt, or West Indies) or from European mines where the disease is found; and (2) lack of sanitary arrangements when such men work in mines.

Conditions favourable to the disease.—1. Temperature exceeding 68° F. Dr. Boycott and Dr. Haldane have hatched out fully developed larvæ at temperatures as low as 60°. The disease may claim greater attention in the future as all new workings will be very deep, 800 or 1000 yards or more. In these cases the temperature will be much higher than the minimum required. The temperature of a mine also depends upon ventilation, so that if there is any slackness in attention to this matter, even in what is regarded as a cold mine, we may find at times the temperature sufficiently high to favour the development of the larvæ. 2. Moisture is an essential factor for the development of the ova and the growth of the larvæ. In the deepest pits, which are regarded by mining engineers as dry, water may be found sometimes. If the watering of the roadways be made compulsory this condition will always be present in every mine so watered. 3. Lack of sanitary arrangements in mine.

Prevention.—1. By providing suitable sanitary arrangements. This point will be referred to in detail further on in this paper. 2. By forbidding miners to relieve themselves along the permanent roadways and in places where the fæcal matter may be trodden about. 3. By the miners taking the precaution to wrap up their food in paper when handling it and thus keep it free from contamination. 4. By the rigid exclusion of those men who are known to be infected. 5. By the medical examination of all men who apply for work at mines and who are known to have been in countries where the disease exists.

Relaxation of efforts to deal with this disease may be attended with grave dangers. The following points may be worthy of notice under this heading:—1. The miners may be infected without showing any symptoms. 2. No mine should be assumed to be free from ankylostomiasis unless a careful inspection has been made and negative results found. 3. An epidemic of ankylostomiasis does not break out in a few days like influenza. Infection may be present in the mine for a considerable period of time and an epidemic follows when there arise conditions which are more favourable to its development.

To give an idea of the extent to which this disease may spread, I would like to remind you that in 1903 in Westphalia, even after considerable improvements had been made in consequence of stringent regulations, out of 188,730 working miners no less than 17,161 were affected by this malady, which is equivalent to 9·09 per cent. In Belgium this subject engaged the attention of the International Congress of Miners and the International Hygienic Congress, both of which were held in Brussels in 1903, and it was stated that 10,000 miners around Liége were suffering from ankylostomiasis; this represents about 30 per cent. of the whole mining community in this district. Dr. Barbier has shown that in the vicinity of Liége 49 pits were infected out of 72 and 23 were immune or had only a single case of the disease. In Austria it was found at Brunnberg, a mining centre, that no less than 85 per cent. of the miners were infected in 1896. With the most strenuous precautions and the establishment of a hospital for the treatment of sufferers the percentage of patients declined to 47 per cent. in 1898, 26 per cent. in 1899, 23 per cent. in 1900, 12 per cent. in 1901, to 8 per cent. in 1902.

Typhoid Fever among Miners.

It has been observed for some years that colliers have been predisposed to contracting typhoid fever through the lack of sanitary arrangements in mines and through the infective exhalations being carried by air currents along the roadways and workings of the mines, and several Local Government Board reports have been issued from 1889 onwards dealing with this subject. But the most important report on this matter has been issued this year by Dr. R. Deane Sweeting, who deals with the prevalence of typhoid fever in the borough of Leigh. This town has a population of 43,000 people of whom 5000 are working colliers. For many years past typhoid fever has not been absent from the town.

The following table shows the number of notifications of, and of deaths from, typhoid fever since 1899:—

TABLE I.

Year.	Notification.	Deaths.	Year.	Notification.	Deaths.
1899	47	9	1904	35	12
1900	57	2	1905	37	11
1901	34	8	1906	49	14
1902	49	13	1907 (to Sept. 30th)	26	5
1903	46	12			

Table II. shows the number of cases of typhoid fever notified from 1902 to 1906 and also the number of colliers affected:—

TABLE II.

Year.	Total number of notifications.	Number of colliery employees notified.
1902	49	13
1903	46	17
1904	35	12
1905	37	11
1906	49	17
1902–1906	216	70
Average per year	43	14

Table III. shows that the incidence of typhoid fever on the collier population of Leigh is four times that on the non-collier population:—

TABLE III.

	Population.	Average yearly incidence of fever.	Rate per 1000.
Colliers	5,049	14	2·8
Non-colliers	38,267	29	0·7
Whole borough	43,316	43	1·0

Dr. Sweeting attributes this fourfold greater incidence among colliers as compared with the rest of the inhabitants as mainly due to the conditions of excrement disposal which obtain at the various collieries at which the men work. There are seven collieries within the borough of Leigh and at four of these there were no provisions made underground, excrement being voided anywhere and anyhow. At one colliery there were a dozen wooden boxes provided for 620 workers, but the conditions which prevailed at the remaining two collieries were distinctly better, improvements having been instituted since the outbreak of ankylostomiasis in Cornwall.

It is now common knowledge that a typhoid patient may remain an effective carrier of the disease for a long period of time and it would appear that the underground workings of a mine afford ideal conditions for the dissemination of the disease.

Present-day Requirements.

These considerations of ankylostomiasis and typhoid fever among miners, as well as the general hygienic aspect of the question, should emphasise the necessity for the sanitation of mines being put upon a satisfactory basis. In making a few suggestions upon the present-day requirements I shall follow the evidence which I had the honour of giving before the Royal Commission on Mines.

There should be proper conveniences at the pit bottom and at convenient points near the main roadways where large numbers of men work. I cannot do better than refer to the arrangements at the Norton Colliery near Stoke-upon-Trent, where Mr. Salt, the manager, has erected closets near the pit bottom and near one of the principal roadways of the mine where a considerable number of men work, and it is purposed to extend the accommodation to other parts of the mine. Each closet is situated in a brick structure provided with a wooden door, and it consists of a galvanised iron pan containing coal-dust placed underneath a wooden seat. The closet near the pit bottom is put in the intake roadway and the other one is placed between the separation doors in a cross cut connecting the main intake with the return crut and each closet is satisfactorily ventilated by an iron pipe placed over the pan and communicating with the return airway. The total cost of a closet, including brickwork, is within £5. The closets are kept in a clean condition by the men and the pans are emptied about twice a week, or oftener if necessary, by one of the horsekeepers, the pans being taken up to the surface and emptied on the waste heap, where they are

Newcastle-upon-Tyne and Northumberland Sanatorium, Barrasford, North Tyne.—Locum Resident Medical Officer, unmarried. Salary £15 a month, with board, residence, and laundry.

North Shields, Tynemouth Victoria Jubilee Infirmary.—House Surgeon. Salary £100 per annum, with rooms, board, &c.

Norwich, Norfolk and Norwich Hospital.—Assistant House Surgeon for six months. Salary £20, with apartments, board, and laundry.

Oldham Infirmary.—Senior House Surgeon. Salary £100 per annum, with board, residence, and washing.

Oldham Union.—Resident Assistant Medical Officer. Salary £130 per annum, with rations, furnished house, washing, and attendance.

Oxford, Radcliffe Infirmary and County Hospital.—Junior House Surgeon, unmarried, for six months. Salary at rate of £40 per annum, with board, &c.

Pendlebury, Manchester Children's Hospital.—Visiting Physician. Honorarium £100 per annum.

Poplar and Stepney Sick Asylum, Bromley, E.—Third Assistant Medical Officer. Salary £120 per annum, with rations, apartments, and washing.

Prestwich County Asylum, Manchester.—Junior Assistant Medical Officer, unmarried. Salary £150, increasing to £250, with board, apartments, and washing.

Queen's Hospital for Children, Hackney-road, Bethnal Green, E.—House Surgeon for six months. Salary at rate of £60 per annum, with board, residence, and laundry.

Rainhill County Asylum, near Liverpool.—Assistant Medical Officer, unmarried. Salary £150 per annum, rising to £250, with further increase to £350, with apartments, board, attendance, and washing.

Rochdale, County Borough of.—Medical Officer of Health. Salary £450, increasing to £550.

Royal London Ophthalmic Hospital, City-road, E.C.—Senior House Surgeon. Salary at rate of £100 per annum, with board and residence.

Royal Navy, Medical Department.—Fifteen Commissions.

Samaritan Free Hospital for Women, Marylebone-road, N.W.—Clinical Assistants.

Scarborough Hospital and Dispensary.—Senior House Surgeon. Salary £100 per annum, with board and residence.

Shrewsbury, Salop Infirmary.—House Physician. Salary at rate of £70 per annum, with board and apartments.

Southampton Free Eye Hospital.—House Surgeon. Salary £100 per annum, with board and residence.

Southampton, Royal South Hants and Southampton Hospital.—Junior House Surgeon for six months. Salary at rate of £80 per annum, with rooms, board, and washing.

Taunton and Somerset Hospital, Taunton.—Resident Assistant House Surgeon for six months. Salary at rate of £50 per annum, with board, lodging, and laundry.

Torosay, Parish of.—Medical Officer. Salary £100 per annum.

Tunbridge Wells General Hospital.—House Surgeon, unmarried. Salary £100 per annum, with board, apartments, and attendance.

Warrington Infirmary and Dispensary.—Junior House Surgeon, unmarried. Salary £100 per annum, with residence and board.

West London Hospital and Post-Graduate College, Hammersmith-road, W.—Clinical Assistants. Also Casualty Officers for three months.

Winsley, near Bath, Three Counties Sanatorium for Consumptives.—Resident Medical Officer, unmarried. Salary £200, rising to £300.

The Chief Inspector of Factories, Home Office, S.W., gives notice of vacancies as Certifying Surgeons under the Factory and Workshop Act at Invergordon, in the county of Ross and Cromarty; at Chatteris, in the county of Cambridge; at Higham Ferrers, in the county of Northampton; at Enniscorthy, in the county of Wexford; and at Rothes, in the county of Elgin.

Births, Marriages, and Deaths.

BIRTHS.

Alford.—On Sept. 7th, at Stafford Lodge, Weston-super-Mare, the wife of H. T. Marmaduke Alford, L.R.C.P. Lond., M.R.C.S. Eng., of a son.

Furnivall.—On Sept. 12th, at Highfield-terrace, Halifax, the wife of Captain C. H. Furnivall, R.A.M.C., of a son.

Mounsey.—On Sept. 13th, at Moorlands, Camberley, the wife of Ridley Ewart Mounsey, M.R.C.S., L.R.C.P., of a daughter.

Taylor.—On Sept. 8th, at Eaton Hill, Norwich, the wife of Sidney Johnson Taylor, M.B., M.R.C.S., of a daughter.

MARRIAGES.

Partridge—Vandermin.—On Sept. 12th, at St. George's, Camberwell, Victor Stanley Partridge, L.R.C.P. Lond., M.R.C.S., M. & L.S.A., to Florence Gertrude, second daughter of the late Petrus Vandermin and Mrs. Vandermin.

Ward—Stoop.—On Sept. 12th, at the parish church, Byfleet, Vere Godsalve Ward, M.D., to Janey Corry, second daughter of Fred C. Stoop.

DEATHS.

Eustace.—On Sept. 10th, at Bournemouth, Fleet-Surgeon Richard Eustace, M.D., R.N., aged 75 years.

Paton.—On Sept. 10th, Edward Percy Paton, M.D., M.S., F.R.C.S., aged 41 years.

Ray.—On Sept. 10th, at Tunbridge Wells, Charles Ray, M.D., M.R.C.S., aged nearly 95 years.

N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Notes, Short Comments, and Answers to Correspondents.

SHAKESPEARE ON SYPHILIS.

To the Editor of THE LANCET.

SIR,—It would be difficult to point to any great author, not himself a physician, in whose works the healing art is referred to more frequently and more respectfully than those of Shakespeare, the sacred writings alone being excepted. Any careful student of the immortal dramatist, who bears, as Hallam says, "the greatest name in all literature," must be struck with the amount of attention paid to subjects of medical interest, scarcely if at all inferior to that which has served as the basis of the ingenious argument, supported by Lord Campbell and others, that this intellectual king of men had devoted seven years of his life to the study of law. Without entering into an argument on this point, i might be interesting to take but a single example of disease referred to in his writings to see what an up-to-date knowledge he possessed on this as on all other subjects.

In *Timon of Athens*, Act. IV., Scene 3, we find a complete list of the secondary effects of venereal virus uttered by the mad misanthropist against Phrynia and Timandra the mistresses of Alcibiades who together visit Timon in the woods near Athens whither he has retreated.

> *Timon*: Consumptions sow
> In hollow bones of man; strike their sharp shins,
> And mar men's spurring. Crack the lawyer's voice,
> That he may never more false title plead,
> Nor sound his quillets shrilly; hoar the flamen,
> That scolds against the quality of flesh,
> And not believes himself: down with the nose,
> Down with it flat; take the bridge quite away
> Of him, that his particular to foresee,
> Smells from the general weal: make curl'd pate ruffians bald;
> And let the unscarred braggarts of the war
> Derive some pain from you: plague all;
> That your activity may defeat and quell
> The source of all erection.—There's more gold:
> Do you damn others, and let this damn you,
> And ditches grave you all!

It has been thought probable that "consumptions in the hollow bones" means disease of the bones of the cranium, which has been called the hollow bone of the body. Diseases of these bones we know to have been terribly frequent in olden time, when the treatment of syphilis was not nearly so effectual as it is now. Painful nodes on the shin bones are, no doubt, meant by the expression, "Strike their sharp shins." The subsequent symptom may be read as we give it, "mar men's spurring," and refer to the victim's inability to use the spurs on horseback, or it may be rendered "mar men's sparring," and taken to mean that they would prevent men from using those kicks on the shin which formed part of the movement of attack and defence in wrestling.

Venereal ulcers of the larynx are next referred to; "crack the lawyer's voice." That hideous disfigurement of chronic syphilis, loss of the nose, is mentioned and even the structure is dealt with "take the bridge quite away." The fearful list of the effects of the virus of syphilis is concluded by impotence and baldness; the last of which is especially remarkable as it was not observed to be a symptom of the complaint until a date shortly before Shakespeare wrote. We learn from Fallopius, upon whose information we may rely, that the loss of hair was not observed to be a symptom of the complaint before 1536, when the disorder had been known for about 40 years—Fernelius being the first to notice it. It is also worth noting that these two symptoms—impotence and loss of the nose, which the dramatist mentions, were omitted by Nicholas Brassa in a work on syphilis, founded almost wholly from his own experience. He jumbles together the primary and secondary manifestations while Shakespeare in this remarkable passage mentions the secondary and tertiary forms of the disease only. That this is from knowledge and not from ignorance seems certain, since in an earlier passage of the same scene he refers to the primary symptoms.

While the discussion of such subjects is allowable in a medical journal one would be rather shocked to find such a passage even from the pen of a great writer in the popular literature of to-day. We must remember, however, that in Shakespeare's time both the novelty and the ravages of this disease attracted to it a larger share of public and private attention than any other disease, except, perhaps, the epidemics which were at that time so frequent and so fatal.

The wide prevalence and the horrible nature of these "rotten diseases of the South" are referred to in Hamlet in the grave digging scene.

> *Hamlet*: How long will a man lie i' the earth ere he rot?
> *Clown*: I'faith, if he be not rotten before he die, (as we have many pocky corses now-a-days, that will scarce hold the laying in,) he will last you some eight year or nine year.

In Wunderlick's "History of Medicine" it is stated that Girtanner had recorded 253 separate treatises which had been written on this disease before the end of the sixteenth century, a fact significant of the anxiety and attention which it excited in the profession.

a condition known as eosinophilia in those who are infected, whether they show symptoms or not.

Method of infection of mine.—This is brought about by (1) the mine becoming infected by men who have brought disease home from countries where it is endemic (for example, soldiers from India, Egypt, or West Indies) or from European mines where the disease is found; and (2) lack of sanitary arrangements when such men work in mines.

Conditions favourable to the disease.—1. Temperature exceeding 68° F. Dr. Boycott and Dr. Haldane have hatched out fully developed larvæ at temperatures as low as 60°. The disease may claim greater attention in the future as all new workings will be very deep, 800 or 1000 yards or more. In these cases the temperature will be much higher than the minimum required. The temperature of a mine also depends upon ventilation, so that if there is any slackness in attention to this matter, even in what is regarded as a cold mine, we may find at times the temperature sufficiently high to favour the development of the larvæ. 2. Moisture is an essential factor for the development of the ova and the growth of the larvæ. In the deepest pits, which are regarded by mining engineers as dry, water may be found sometimes. If the watering of the roadways be made compulsory this condition will always be present in every mine so watered. 3. Lack of sanitary arrangements in mine.

Prevention.—1. By providing suitable sanitary arrangements. This point will be referred to in detail further on in this paper. 2. By forbidding miners to relieve themselves along the permanent roadways and in places where the fæcal matter may be trodden about. 3. By the miners taking the precaution to wrap up their food in paper when handling it and thus keep it free from contamination. 4. By the rigid exclusion of those men who are known to be infected. 5. By the medical examination of all men who apply for work at mines and who are known to have been in countries where the disease exists.

Relaxation of efforts to deal with this disease may be attended with grave dangers. The following points may be worthy of notice under this heading:—1. The miners may be infected without showing any symptoms. 2. No mine should be assumed to be free from ankylostomiasis unless a careful inspection has been made and negative results found. 3. An epidemic of ankylostomiasis does not break out in a few days like influenza. Infection may be present in the mine for a considerable period of time and an epidemic follows when there arise conditions which are more favourable to its development.

To give an idea of the extent to which this disease may spread, I would like to remind you that in 1903 in Westphalia, even after considerable improvements had been made in consequence of stringent regulations, out of 188,730 working miners no less than 17,161 were affected by this malady, which is equivalent to 9·09 per cent. In Belgium this subject engaged the attention of the International Congress of Miners and the International Hygienic Congress, both of which were held in Brussels in 1903, and it was stated that 10,000 miners around Liége were suffering from ankylostomiasis; this represents about 30 per cent. of the whole mining community in this district. Dr. Barbier has shown that in the vicinity of Liége 49 pits were infected out of 72 and 23 were immune or had only a single case of the disease. In Austria it was found at Brunnberg, a mining centre, that no less than 85 per cent. of the miners were infected in 1896. With the most strenuous precautions and the establishment of a hospital for the treatment of sufferers the percentage of patients declined to 47 per cent. in 1898, 26 per cent. in 1899, 23 per cent. in 1900, 12 per cent. in 1901, to 8 per cent. in 1902.

Typhoid Fever among Miners.

It has been observed for some years that colliers have been predisposed to contracting typhoid fever through the lack of sanitary arrangements in mines and through the infective exhalations being carried by air currents along the roadways and workings of the mines, and several Local Government Board reports have been issued from 1889 onwards dealing with this subject. But the most important report on this matter has been issued this year by Dr. R. Deane Sweeting, who deals with the prevalence of typhoid fever in the borough of Leigh. This town has a population of 43,000 people of whom 5000 are working colliers. For many years past typhoid fever has not been absent from the town.

The following table shows the number of notifications of, and of deaths from, typhoid fever since 1899:—

TABLE I.

Year.	Notification.	Deaths.	Year.	Notification.	Deaths.
1899	47	9	1904	35	12
1900	57	2	1905	37	11
1901	34	8	1906	49	14
1902	49	13	1907 (to Sept. 30th)	26	5
1903	46	12			

Table II. shows the number of cases of typhoid fever notified from 1902 to 1906 and also the number of colliers affected:—

TABLE II.

Year.	Total number of notifications.	Number of colliery employees notified.
1902	49	13
1903	46	17
1904	35	12
1905	37	11
1906	49	17
1902–1906	216	70
Average per year	43	14

Table III. shows that the incidence of typhoid fever on the collier population of Leigh is four times that on the non-collier population:—

TABLE III.

	Population.	Average yearly incidence of fever.	Rate per 1000.
Colliers	5,049	14	2·8
Non-colliers	38,267	29	0·7
Whole borough	43,316	43	1·0

Dr. Sweeting attributes this fourfold greater incidence among colliers as compared with the rest of the inhabitants as mainly due to the conditions of excrement disposal which obtain at the various collieries at which the men work. There are seven collieries within the borough of Leigh and at four of these there were no provisions made underground, excrement being voided anywhere and anyhow. At one colliery there were a dozen wooden boxes provided for 620 workers, but the conditions which prevailed at the remaining two collieries were distinctly better, improvements having been instituted since the outbreak of ankylostomiasis in Cornwall.

It is now common knowledge that a typhoid patient may remain an effective carrier of the disease for a long period of time and it would appear that the underground workings of a mine afford ideal conditions for the dissemination of the disease.

Present-day Requirements.

These considerations of ankylostomiasis and typhoid fever among miners, as well as the general hygienic aspect of the question, should emphasise the necessity for the sanitation of mines being put upon a satisfactory basis. In making a few suggestions upon the present-day requirements I shall follow the evidence which I had the honour of giving before the Royal Commission on Mines.

There should be proper conveniences at the pit bottom and at convenient points near the main roadways where large numbers of men work. I cannot do better than refer to the arrangements at the Norton Colliery near Stoke-upon-Trent, where Mr. Salt, the manager, has erected closets near the pit bottom and near one of the principal roadways of the mine where a considerable number of men work, and it is purposed to extend the accommodation to other parts of the mine. Each closet is situated in a brick structure provided with a wooden door, and it consists of a galvanised iron pan containing coal-dust placed underneath a wooden seat. The closet near the pit bottom is put in the intake roadway and the other one is placed between the separation doors in a cross cut connecting the main intake with the return crut and each closet is satisfactorily ventilated by an iron pipe placed over the pan and communicating with the return airway. The total cost of a closet, including brickwork, is within £5. The closets are kept in a clean condition by the men and the pans are emptied about twice a week, or oftener if necessary, by one of the horsekeepers, the pans being taken up to the surface and emptied on the waste heap, where they are

Medical Diary for the ensuing Week.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

POST-GRADUATE COLLEGE, West London Hospital, Hammersmith-road, W.

MONDAY.—2 P.M., Medical and Surgical Clinics. X Rays. Dr. K. Scott: Diseases of the Eyes. 2.30 P.M., Operations.

TUESDAY.—2 P.M., Medical and Surgical Clinics. X Rays. Diseases of the Throat, Nose, and Ear. 2.30 P.M., Operations. Dr. Abraham: Diseases of the Skin.

WEDNESDAY.—10 A.M., Dr. Saunders: Diseases of Children. Diseases of the Throat, Nose, and Ear. 2 P.M., Medical and Surgical Clinics. X Rays. Dr. K. Scott: Diseases of the Eyes. 2.30 P.M., Operations. Dr. Robinson: Diseases of Women.

THURSDAY.—2 P.M., Medical and Surgical Clinics. X Rays. Dr. K. Scott: Diseases of the Eyes. 2.30 P.M., Operations.

FRIDAY.—2 P.M., Medical and Surgical Clinics. X Rays. Diseases of the Throat, Nose, and Ear. 2.30 P.M., Operations. Dr. Abraham: Diseases of the Skin.

SATURDAY.—10 A.M., Dr. Saunders: Diseases of Children. Diseases of the Throat, Nose, and Ear. 2 P.M., Medical and Surgical Clinics. X Rays. Dr. K. Scott: Diseases of the Eyes. 2.30 P.M., Operations. Dr. Robinson: Diseases of Women.

MONDAY.—4 P.M., Dr. H. G. Adamson: Clinique (Skin).

TUESDAY.—4 P.M., Dr. J. E. Squire: Clinique (Medical)

WEDNESDAY.—4 P.M., Mr. R. Johnson: Clinique (Surgical).

THURSDAY.—4 P.M., Mr. Hutchinson: Clinique (Surgical).

FRIDAY.—4 P.M., Mr. Stuart-Low: Clinique (Ear).

OPERATIONS.

METROPOLITAN HOSPITALS.

MONDAY (21st).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), St. George's (2 P.M.), St. Mary's (2.30 P.M.), Middlesex (1.30 P.M.), Westminster (2 P.M.), Chelsea (2 P.M.), Samaritan (Gynæcological, by Physicians, 2 P.M.), Soho-square (2 P.M.), City Orthopædic (4 P.M.), Gt. Northern Central (2.30 P.M.), West London (2.30 P.M.), London Throat (9.30 A.M.), Royal Free (2 P.M.), Guy's (1.30 P.M.), Children, Gt. Ormond-street (9 A.M.), St. Mark's (2.30 P.M.).

TUESDAY (22nd).—London (2 P.M.), St Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), Guy's (1.30 P.M.), Middlesex (1.30 P.M.), Westminster (2 P.M.), West London (2.30 P.M.), University College (2 P.M.), St. George's (1 P.M.), St. Mary's (1 P.M.), St. Mark's (2.30 P.M.), Cancer (2 P.M.), Metropolitan (2.30 P.M.), London Throat (9.30 A.M.), Samaritan (9.30 A.M. and .30 P.M.), Throat, Golden-square (9.30 A.M.), Soho-square (2 P.M.), Chelsea (2 P.M.), Central London Throat and Ear (2 P.M.), Children, Gt. Ormond-street (9 A.M. and 2 P.M.), Ophthalmic (2 P.M.), Tottenham (2.30 P.M.).

WEDNESDAY (23rd).—St. Bartholomew's (1.30 P.M.), University College (2 P.M.), Royal Free (2 P.M.), Middlesex (1.30 P.M.), Charing Cross (3 P.M.), St. Thomas's (2 P.M.), London (2 P.M.), King's College (2 P.M.), St. George's (Ophthalmic, 1 P.M.), St. Mary's (2 P.M.), National Orthopædic (10 A.M.), St. Peter's (2 P.M.), Samaritan (9.30 A.M. and 2.30 P.M.), Gt. Northern Central (2.30 P.M.), Westminster (2 P.M.), Metropolitan (2.30 P.M.), London Throat (9.30 A.M.), Cancer (2 P.M.), Throat, Golden-square (9.30 A.M.), Guy's (1.30 P.M.), Royal Ear (2 P.M.), Royal Orthopædic (3 P.M.), Children, Gt. Ormond-street (9 A.M. and 9.30 A.M., Dental, 2 P.M.), Tottenham (Ophthalmic, 2.30 P.M.), West London (2.30 P.M.).

THURSDAY (24th).—St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), University College (2 P.M.), Charing Cross (3 P.M.), St. George's (1 P.M.), London (2 P.M.), King's College (2 P.M.), Middlesex (1.30 P.M.(, St. Mary's (2.30 P.M.), Soho-square (2 P.M.), North-West London (2 P.M.), Gt. Northern Central (Gynæcological, 2.30 P.M.), Metropolitan (2.30 P.M.), London Throat (9.30 A.M.), Samaritan (9.30 A.M. and 2.30 P.M.), Throat, Golden-square (9.30 A.M.), Guy's (1.30 P.M.), Royal Orthopædic (9 A.M.), Royal Ear (2 P.M.), Children, Gt. Ormond-street (9 A.M. and 2 P.M.), Tottenham (Gynæcological, 2.30 P.M.), West London (2.30 P.M.).

FRIDAY (25th).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), Guy's (1.30 P.M.), Middlesex (1.30 P.M.), Charing Cross (3 P.M.), St. George's (1 P.M.), King's College (2 P.M.), St. Mary's (2 P.M.), Ophthalmic (10 A.M.), Cancer (2 P.M.), Chelsea (2 P.M.), Gt. Northern Central (2.30 P.M.), West London (2.30 P.M.), London Throat (9.30 A.M.), Samaritan (9.30 A.M. and 2.30 P.M.), Throat Golden-square (9.30 A.M.), City Orthopædic (2.30 P.M.), Soho-square (2 P.M.), Central London Throat and Ear (2 P.M.), Children, Gt. Ormond-street (9 A.M., Aural, 2 P.M.), Tottenham (2.30 P.M.), St. Peter's (2 P.M.).

SATURDAY (26th).—Royal Free (9 A.M.), London (2 P.M.), Middlesex (1.30 P.M.), St. Thomas's (2 P.M.), University College (9.15 A.M.), Charing Cross (2 P.M.), St. George's (1 P.M.), St. Mary's (10 A.M.), Throat, Golden-square (9.30 A.M.), Guy's (1.30 P.M.), Children, Gt. Ormond-street (9 A.M. and 9.30 A.M.), West London (2.30 P.M.).

At the Royal Eye Hospital (2 P.M.), the Royal London Ophthalmic (10 A.M.), the Royal Westminster Ophthalmic (1.30 P.M.), and the Central London Ophthalmic Hospitals operations are performed daily

EDITORIAL NOTICES.

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITOR," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention should be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this office.

Lectures, original articles, and reports should be written on one side of the paper only, AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers—not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale and advertising departments of THE LANCET *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

MANAGER'S NOTICES.

TO SUBSCRIBERS.

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, London, W.C., are dealt with by them? Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid, and *not* to THE LANCET Offices.

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will insure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

THE COLONIAL AND FOREIGN EDITION (*printed on thin paper*) is published in time to catch the weekly Friday mails *to all parts of the world.*

The rates of subscriptions, post free, either from THE LANCET Offices or from Agents, are:—

FOR THE UNITED KINGDOM.		TO THE COLONIES AND ABROAD.	
One Year	£1 12 6	One Year	£1 14 8
Six Months	0 16 3	Six Months	0 17 4
Three Months	0 8 2	Three Months	0 8 8

Subscriptions (which may commence at any time) are payable in advance. Cheques and Post Office Orders (crossed "London and Westminster Bank, Westminster Branch") should be made payable to the Manager, Mr. CHARLES GOOD, THE LANCET Offices, 423, Strand, London, W.C.

TO COLONIAL AND FOREIGN SUBSCRIBERS.

SUBSCRIBERS ABROAD ARE PARTICULARLY REQUESTED TO NOTE THE RATES OF SUBSCRIPTIONS GIVEN ABOVE. It has come to the knowledge of the Manager that in some cases higher rates are being charged, on the plea that the heavy weight of THE LANCET necessitates additional postage above the ordinary rate allowed for in the terms of subscriptions. Any demand for increased rates, on this or on any other ground, should be resisted. The Proprietors of THE LANCET have for many years paid, and continue to pay, the whole of the heavy cost of postage on overweight foreign issues; and Agents are authorised to collect, and generally do so collect, from the Proprietors the cost of such extra postage.

The Manager will be pleased to forward copies direct from the Offices to places abroad at the above rates, whatever be the weight of any of the copies so supplied. Address—THE MANAGER, THE LANCET OFFICES, 423, STRAND, LONDON, ENGLAND.

known in dilute solution; it is said to occur in the chlorophyll cells of all plants and to form an unstable product in the unsolved synthetic process of conversion by the plant of the carbonic acid gas of the air into carbohydrates.

Formaldehyde is a powerful reducing agent and by its combination with oxygen forms formic acid, whereas by reduction it becomes converted into methyl alcohol. By *evaporation formaldehyde is* converted into a polymeric body, paraformaldehyde. Polymerisation is one of formaldehyde's most characteristic properties; when an aqueous solution is treated with a weak alkali there is produced a polymer formose. (What a field for therapeutic romance!)

Formates, or salts of formic acid, are decomposed by dilute mineral acids yielding formic acid. N.B.—Whether the dilute HCl secretion of the stomach converts the glyceroformates into formic acid I *do not know, but I would assert* that the alkali of the pancreatic juice would soon reconvert any such formic acid into alkali formates.

Formic acid blisters the skin and acts like a weak mineral acid, so that I do not see why its use should be any more exploited than the long-employed and well-known mineral acids, HCl, HNO_3, H_2SO_4, which have long yielded to the more accurate delineations of the knife and more penetrating but less diffusing cauterisation by the use of the easily adjustable thermo- and electro-cautery. Like formaldehyde, formic acid possesses reducing properties.

Formalin has long enjoyed a just reputation as a preservative and, by virtue of its antiseptic and drying properties, is much used as a topical application to ulcerative lesions. Do the enthusiasts of the vaunted formic acid cure for cancer *think that when formalin comes in contact with necrotic* tissues it is converted into formic acid? Or will they shortly advance that formic acid, taken by the mouth and subsequently absorbed, circulates in the blood but at the cancerous focus becomes reduced to formaldehyde, here, concentrated and nascent, to serve the dual purpose of a destroying demon to the cancer cell but of a guardian angel to the normal cells of the tissue. The potency of a drug introduced into the systemic circulation to destroy the cancer cell—a living cell—and yet leave unscathed the normal cell of the *tissue infers a selective process with which I am not* familiar.

Quinine does not limit its powers of primary retardation and final stagnation of the varying changes in the life-history of the "plasmodium malariæ" without affecting the *cellular elements of the blood.* Why, every student of medicine is taught to observe the phenomenon of negative chemiotaxis and the inhibition of amœboid movements as induced by the action of a solution of quinine upon the leucocyte!

The *extensive use of iodides depends, first,* on their diffusibility, but secondly upon the readiness with which the halogen salt of the lesion-producing toxin is formed, so that I believe, before many years, the therapeutic action of the halogen bodies will be accurately determined and equated chemically.

The following cases, proved to be carcinoma by microscopical investigation in corroboration of clinical deductions, have been treated by one or more of the preparations or applications referred to above:—

CASE 1.—Patient aged 53 years. Carcinoma *cervicis uteri.* Much pain. Owing to distaste for the infusion of nettle such was discontinued after six weeks. *Formalin douches.* No benefit obtained from this treatment. Progressive cachexia. *Death.*

CASE 2.—Patient aged 42 years. Carcinoma cervicis uteri. No pain. Marked cachexia. Infusio A.F. Formalin douches. No benefit. Death.

CASE 3.—Patient aged 47 years. Carcinoma linguæ. Constant sipping of infusion of fresh nettle for four months. *Formamint tablets.* No check to the progressive course of his malady obtained by such medicaments. Death.

CASE 4.—Patient aged 50 years. Carcinoma laryngis. Previously treated at a special hospital for diseases of the throat. Pain progressive, now intolerable. Insomnia. Infusio A.F. constantly imbibed for six weeks with neither relief from pain thereby nor diminution of the growth. Formamint tablets. Death.

CASE 5.—Patient aged 54 years. Advanced carcinoma cervicis uteri. Formic acid by the mouth. Formalin douches and *fomentations of* nettles regularly employed from May 29th to July 31st without any amelioration to the progressive fatal *course of the* disease.

CASE 6.—Patient aged 62 years. Cancer of floor of mouth. This man had been an *in-patient at one of our* large general hospitals under the care of an eminent surgeon. The patient stated that he felt better while in hospital

of the lum

drank "net

were in no way alleviated.

In each of the above cases the treatment was systematically conducted under favourable dietetic and hygienic conditions. In each case the progress was unchecked and the issue definite. Of course, the breath was less obnoxious when formamint tablets were sucked and the vaginal discharges were less offensive when formalin douches were employed.

The therapy of formic acid is no new and wondrous discovery which has come to emancipate us from the terrible disease cancer. The diuretic and irritating action of the urticaceæ have long been known; indeed, urtication is a term applied to flagellation with nettles which was a method *of treatment once employed for paralysis.* This crude method probably found out the malingerer with as much success as modern procedures. Again, infusion of nettles ("nettle-tea") is commonly drunk by country folk when the young succulent herb can be plucked; whereas "nettle-beer," an *ancient summer beverage* entailing some housewifery in its brewing owing to the essential proportions of added ingredients, of which buck-bean, yeast, and certain salts are most important, and demanding a timely perception of the adequate fermentation, is much drunk by haymakers. I know a family who have *regularly for the past* 40 years brewed their weekly quantity of nettle-beer, which has been their chief beverage at dinner and supper for four months every year, yet cancer has attacked these temperate folk despite their hygienic surroundings. Of this family the mother *died from Bright's disease about* 20 years ago; the father died from cancer of the rectum three years ago; the elder daughter was operated on by me in 1903 for cancer of the right breast and is to-day clinically free from all traces of cancer; and the younger daughter *is living.*

In one of the wildest parts *of Wales there lived to nearly* 90 years of age a keen-witted and observant farmer's wife who was in her lifetime well known to me and whose fame as a herbalist was widely spread in those regions of "Gwalia." Infusions and fomentations of nettle were among her *pharmaceutical armamentarium;* these in particular she applied after a more energetic treatment to such cancerous conditions as rodent ulcer, epithelioma of the lip, tongue, and hand—which malignant papillary growths she termed "dafad wyllt," or wild wart. The more energetic treatment, *dexterously carried* out by her gentle hands, was the actual cautery—a kitchen poker, a large nail, or a knitting-needle heated to redness in the fire, before which the patient sat, was driven deeply into the lesion and repeatedly if deemed correct—to be followed by a sterilised dressing of molten lard and a burnt rag. Her cures were numerous and, needless for me to state, were due to the cautery and not to the subsequent nettle concoctions *and applications.*

If formic acid has these beneficial effects why is acetic acid, one of the same homologous series of organic compounds, held out by many medical men as a cause of an antecedent state productive of cancer of the stomach? Again, if this acid of the *lowest* of the methane or *paraffin series* is a cure, why have clinicians through many ages taught that the higher members of this paraffin series are a causative factor in sweeps' cancer?

I feel no hesitation in adding that no authentic case of *carcinoma, as recognised clinically* and confirmed by an expert microscopist, has as yet been expurged by ingestion of formic acid.

Berkeley-square, W.

A CASE OF RUPTURED UTERUS.

BY ALICE M. SORABJI, B.SC. BOMBAY, M.B., B.S. LOND.,
DOCTOR IN CHARGE, VICTORIA ZENANA HOSPITAL, DELHI, INDIA.

THE patient was an Englishwoman, aged 24 years, who came to me five weeks *after parturition* complaining of general lassitude and pain *over* the lower part of the abdomen, with exacerbations at *intervals. She had come* in from an out-station and was only brought to see me on her way home. On examination the abdomen was *found to be* very tender below the level of the umbilicus, and per vaginam the cervix was soft, the os admitted two fingers, and the sound went in five inches and abutted against a soft mass at the fundus. There was a good deal of discharge which had an unpleasant *odour.* The patient was *induced to stay* in the hospital and was prepared for curettage the next *day.*

At the operation there was naturally no need *for dilatation* and the blunt *curette* was inserted at once and some blood

An Address

ON

ITCHING: ITS CAUSES AND TREATMENT.

Delivered to the Edinburgh Post-Graduate Vacation Course in Medicine on Sept. 15th, 1908,

BY W. ALLAN JAMIESON, C.M., M.D. EDIN.,

SURGEON, THE KING'S BODYGUARD FOR SCOTLAND, THE ROYAL COMPANY OF ARCHERS; CONSULTING PHYSICIAN FOR DISEASES OF THE SKIN, EDINBURGH ROYAL INFIRMARY.

GENTLEMEN,—Everyone knows from personal experience what itchiness is, but when it comes to define the sensation in words a difficulty arises. It is not pain. Indeed, pain is in some respects the antithesis of itchiness, and while in quite a minor development, that of tickling, the impression may approach the agreeable, its persistence even for a brief period is not pleasurable. Reduced to its simplest terms it conveys the idea to consciousness of some insect impinging on or crawling over the skin, immediately succeeded by the involuntary desire or effort to dislodge the offender. So vivid is this conviction in some cases that the individual can scarcely be persuaded that there is not a material cause for his annoyance. Hence the term formication or the procession of ants has been attached to a variety. The specialised sense of touch still retains traces of the time when it was not differentiated from common sensation. We may therefore interpret itching as "a functional disorder of innervation which may be produced by external or internal causes alike." Itching or pruritus is essentially a surface sensation, and Bronson, who has most deeply studied the subject, is disposed to locate it in the epidermis. Assuredly its most marked developments are to be found in those lesions which mainly affect the epidermis. Thus the tingling characteristic of nettle-rash may precede the eruption of the wheal if it is not coincident with its appearance. It is just when an abrasion or a wound is finally cicatrising that itching, popularly regarded as a favourable sign, is experienced. Pressure is inimical to itching. When slight it may not exert much influence in this direction, but firm pressure, however exercised, annuls the sensation for the time. The tormenting itching in scabies is caused by the female acarus driving her tunnel through the epidermis.

We may have intense itching with entire absence of any definite skin disease, and this we may call essential pruritus, or we may have it in direct association with some accredited lesion or integumentary ailment. It occurs as a superficial manifestation in both. When encountered over or near varicose veins it is the surface innervation which is disturbed. The proximate cause of itching is closely connected with that of urticaria, more particularly that form known as urticaria factitia or dermographism, where the vaso-motor mechanism is so sensitive that wheals can be evoked at will by friction, such as drawing the edge of a paper-knife across the skin, with slight pressure. Unna has enunciated the theory that itching is due to a disproportion between the pressure of the tissue juices and that of the limiting corneous layer. He explains the relief afforded by scratching as at least partly referable to the escape of serum from lacerations inflicted by the nails, temporarily equalising the tension. But this theory will not wholly account for itching in cases where there is no evidence of œdema, as in senile pruritus, where the integument is often fine, polished, and satiny. In such individuals, in addition to atrophy and thinning of the skin, there can almost always be traced an inactivity or complete arrest of perspiration. Many have never perspired freely all their lives; in others the diminution has been so gradual that a point is reached where the skin scarcely becomes moist even in hot rooms or warm weather. That this has much to do with the incidence of the pruritus is corroborated by the evidence of treatment, for such remedies as tend to restore sweating *pari passu* relieve the pruritus. We must probably assume in addition wholly to account for the pruritus that there is likewise a degree of hyperæsthesia, an undue sensitiveness of the skin, so that contacts which in ordinary circumstances would be well and easily borne in such persons evoke this peculiar form of irritability. Some are disposed to hold the view that all cases of pruritus senilis are examples of pediculosis, but while pediculi vestimentorum may, and do, find a suitable soil in the integument of the aged, yet there are numerous instances of general itching in the elderly quite unconnected with the presence of these parasites. We must bear in mind also that in old people inactivity, solitariness of life, and enforced leisure, make them conscious of impressions which passed unnoticed when busily engaged. Scratching indulged in to mitigate the sensation is not in itself harmful; it is the degree to which it is carried, not the act itself which is injurious. In civilised life we all, more or less designedly, habitually scratch our skins. The rough towel, the flesh brush, the loofah, used in our bath or after it, by the friction they exercise, have the salutary effect of ridding us of the effete cells of the horny layer of the epidermis. This of course presupposes a healthy and resistant skin, but in disease the same action is deleterious, since the resistance of the organ attacked is lowered. In lichen planus itching is a feature, yet here less harm is done by scratching than in most other ailments. The pigmentation left behind by the involuting papules may certainly be partly due to scratching, just as the darkening of the integument so constantly met with in the case of tramps infected with pediculi. It is singular that there are some diseases almost wholly limited to the epidermis where itching is not complained of. Of such we may cite as examples a parasitic disease, pityriasis versicolor, and an inflammatory one, pityriasis rosea.

But generalised pruritus may be set up by parasites. Lice very commonly occasion it in the aged, or in the alcoholic and careless, even though not old. Since the pediculus lives in the clothes and only attacks the skin for the purpose of feeding, the insect selects situations where the linen lies close to the surface, as at the neck or waist, or where it is little likely to be disturbed, as the back between the scapulæ. As this is a region only with difficulty accessible to the fingers the monks who occupy the monasteries of Mount Athos make and sell special instruments called "back scratchers," probably to relieve the irritation thus caused. These consist of a long, narrow, slightly curved piece of wood bearing at the extremity a minute carved human hand. Bundles were lying for sale in the bazaars of Karyes the capital. Curiously enough, these implements seem unknown in the monasteries in the Peloponnesus, though it is more than doubtful if ablutions are any more frequent, at least inquiries for specimens were fruitless. Fleas come next to lice as a cause of itching from this source, but even the human flea, much less those derived from domestic animals, does not permanently live on his host. The attacks, therefore, of this variety are brief, and idiosyncrasy exerts an important influence. The bug, repulsive as it is, does not occasion any very severe itching though the red bumps it causes are for a time both annoying and disfiguring.

The next stage in itching lies in its occurrence in association with some definite skin disease, and the one with which it is most especially conjoined is undoubtedly eczema. Not with all forms of eczema, however. It is met with in acute erythematous, papular, and scaly eczemas, while it is almost wholly absent in the vesicular and weeping forms. Here Unna's theory finds its strongest confirmation. The adjustment between the pressure of the tissue juices and of the corneous epidermis is disorganised. In many types of chronic eczema itching is also well marked though absent in that attacking the palms and soles. The thinner the epidermis is naturally the more pronounced is the itching in chronic infiltrated eczema. It persists, too, after apparent cure, and is answerable for relapses in eczema in not a few instances, for the scratching which it gives rise to lights up the dormant ailment into activity.

Like insects, plants may set up a dermatitis and induce itching. The rôle played by the primula obconica and sinensis is now well recognised, but Dr. Norman Walker has observed that the humea elegans may, in certain individuals, act in a similar manner.

We know nothing of the true cause of mycosis fungoides, but the early eruptions, eczematous or lichenous in character, which may long precede the evolution of the tumours, raise our suspicions by the persistent itching which accompanies them, an itching which yields to no remedy except the x rays, and even then the relief so afforded is not with certainty lasting. The itching encountered in dermatitis herpetiformis distinguishes it from pemphigus and other

The second indication is to supply pressure, which the loose cells of the extemporised corneous layer do not yet efficiently provide. Hence, where it can be used, Unna's zinc glycerine jelly furnishes this, prevents scratching, advances the cure of the eczema, and obviates itching. The most approved formula runs thus:—

Gelatinæ albæ	30·0
Zinci oxidi...	30·0
Glycerini	50·0
Aquæ	90·0

The glycero-gelatin so compounded is best dispensed in a narrow and deep tin can. This when placed in boiling water allows the jelly to liquefy rapidly, and when it has reached the consistence of milk it can be conveniently painted on the skin. While it is setting the surface should be touched with absorbent cotton-wool, enough of which attaches itself to form a felt-like coating. This plan is especially serviceable in *those localities* which have been mentioned as apt, from the thinness of the integument, to be seats of troublesome *itching*, as the bend of the elbow and the ham.

Weak tarry lotions or varnishes are most advantageously *employed in the final stages*. Patients admit that their eczema to appearance is well, yet complain bitterly that the itching still continues. Then painting with a solution of coal tar in acetone may be helpful.

Picis carbonis	ʒi.
Benzol	ʒiv.
Acetone	℥ii.

The *solution* should be filtered to get rid of particles of undissolved tar, and then a clear brownish fluid is obtained, a thin layer of which is not disfiguring.

In almost all forms of itching in eczema much temporary relief can be got from sopping the part with very hot water for a few minutes, then drying without friction with a fleecy towel. One of the lotions mentioned may be applied immediately to maintain the sedative effect. The itching associated with lichen planus yields, slowly no doubt, to the administration of small and repeated doses of tartrate of antimony in solution, but it is greatly allayed by painting with Boeck's lotion, already mentioned, or by smearing the affected parts, if the eruption is limited in area, with cold cream containing a drachm of chloral camphor to the ounce.

The irritation, culminating in itchiness produced by poisonous plants, may be merely *erythematous*, may proceed to definite dermatitis, with œdema, redness, and heat, or vesiculation may occur. In all these *forms* the most appropriate treatment is that accorded to burns from caloric, plus the neutralisation of the poison introduced into the skin, which is more or less acrid. Hence something of the nature of carron oil is *specially grateful*:—

Ol. amygdalarum }	āā ℥iii.
Liq. calcis ... ... }	
Zinci oxidi ... ... }	āā ʒiv.
Cretæ praeparatae }	
Acidi borici	ʒi.

This suits the erythema and the simple dermatitis. Should blisters or bullæ form then there is no *better way* of dealing with the trouble than by dusting freely with a bland powder—

Acidi borici pulv.	grs. xxv.
Talci pulv.	ʒi.

and enveloping the part in absorbent cotton-wool, secured by a bandage. When the surface has dried up the hard epidermic masses which accumulate must be allowed to separate spontaneously, not picked off prematurely, as is very apt to be done, with a false idea of hastening the cure. With the *removal* of the cause—cessation of contact with the obnoxious plant—and proper management one might conclude that the irritation would disappear, but this is by no means always the case, and hence prolonged care is frequently necessary to get quite rid of the itching in such cases.

In dealing with pruritus ani one has to remember that the state revealed to us on examination is not the original one. The condition of the neighbouring skin has been much altered and modified by scratching, and these secondary phenomena call for special attention. It has been stated that frequently the liver is at fault and hence hepatic stimulants are indicated. Not, however, those coarse, reputed mercurial cholagogues, as calomel, grey powder, or blue pill, relics of an effete system of indiscriminate drugging, still far too often prescribed, but such as euonymin; bismuth, soda, and rhubarb; or the compound sulphur lozenge of Garrod; mild alteratives, far more efficient than the older and rougher ones. Indeed, in all cases it is desirable to procure, either naturally or artificially, an easy, regular, and soft movement of the bowels, avoiding constipation on the one hand as much as anything approaching diarrhœa on the other. This end is reached better by sulphur in some combination than by aloes or cascara. Compound liquorice powder, therefore, suits many persons; others do better with one of the natural aperient *mineral waters containing sulphates, as Hunyadi Janos* or Franz Josef. When there are internal piles a nightly suppository of two grains of hamamelin, continued for a couple of weeks, usually renders them no longer a source of trouble. If there is more general irritability of the rectal mucous membrane, with dilated and varicose venules, an enema composed of two drachms of liquor bismuthi in two ounces of freshly prepared, thin, warm starch, administered at bedtime and retained as long as possible, will prove soothing and healing. Thread worms, if discovered, require lavements of salt-and-water or lime-water. The patient should be advised *to sit habitually on a hard and flat seat and to discard* cushions on his chair. Locally, Lassar's paste, in which one drachm of the zinc is replaced by as much oxychloride of bismuth and without salicylic acid, applied very thinly, is appropriate in most cases. Sometimes a cold cream, having a lanoline base, in which is incorporated a little ammoniated mercury, suits even better:—

Lanolini	ʒv.
Ol. amygdal.	ʒiiss.
Aq. camphoræ	ʒiiss.
Hydrarg. ammoniati	grs. vi.

Immediate temporary relief to the itching is also obtained by occasional painting with a solution of nitrate of silver, ten grains in an ounce of spiritus ætheris nitrosi. At night the disposition to scratch may be prevented by manacling the wrists with a skein of wool arranged as a clove hitch and fastened to the bedstead. In obstinate cases one or two brief exposures to the x rays have been found to exercise a markedly curative effect, but their application must be directed with great caution and circumspection. Finally, for detergent purposes paper, even the finest, is inapplicable, water and a soft sponge being substituted.

In pruritus vulvæ, when glycosuria is present, the condition should be treated on the recognised lines. *In the gouty* form met with in middle-aged women the mineral waters of Contrexeville and Vichy have *proved of service*. The sugar has in many cases wholly and permanently disappeared under their use *between meals*, combined with a pill of codeine, lactucarium, and nux vomica. Locally boric acid in a rather stiffish lanoline cold cream has, as a rule, answered best. In the non-glycosuric cases painting with the solution of nitrate of *silver already* mentioned, washing with menthol soap, and the application of the same boric cold cream have in *most cases* in time proved curative. At night a fold of Beiersdorf's zinc ichthyol salve muslin is both cooling and comfortable, if carefully introduced.

For itching under and between the toes, since this largely depends *on the decomposition* of the perspiration secreted there, careful and daily ablution is to be practised, and after drying a tumenol ointment annuls the sensation. It consists of 48 grains of tumenol in an ounce of cold cream; the sole disadvantage is the dark colour, but this does not so much matter in the case of the feet.

If in the course of your reading you may turn to any of the larger treatises on skin diseases in general, or to some article or lecture appearing in the periodicals on itching in particular, you will find a long array of remedies formulated, and you may perhaps feel disappointed that so few comparatively have been mentioned to-night. It is almost a certain inference that the obstinacy may be gauged by the number of curative agents tabulated, and itching is no exception. It is an obstinate symptom, as the fact of your presence here to listen to what I can tell you testifies. You desire to learn all you can about it. But Mr. Jonathan Hutchinson has sagely observed that it is preferable to know how and when to employ a few remedies than to have a superficial acquaintance with a great many. I have given you the formulæ for, and indicated the mode of using, those as in the preceding case. When the patient left the hospital she was able to walk without pain.

These cases of acquired diffuse painful lipoma of the foot are clearly distinguishable from that form of "gigantism" known as congenital diffuse lipoma, where the affection is characterised by a general hypertrophy of the fatty and subcutaneous tissues, first affecting the toes or fingers. It spreads by direct continuity for a time; but as the hypertrophy increases, isolated masses of fatty material appear at some distance beyond the advancing edges. In time these masses become incorporated with the advancing growth. Incidentally, I should add that the microscopical characters of the congenital diffuse lipoma are entirely different from those seen in the painful acquired form of diffuse lipoma. In the former, while the main part of the section is occupied by fat and areolar tissue, yet the interfibrous spaces are crowded by small round cells, not unlike those seen in round-celled sarcoma. And clinically the diffuse congenital form of lipoma is somewhat akin to sarcoma in that it shows an inveterate tendency to recur very rapidly after removal. In the acquired diffuse form no such appearances are evident, but the blood-vessels are extremely numerous and somewhat hypertrophied. And in connexion with their origin cases are met with which throw some light on this point. Such an one is the following; occurring in a girl, aged 17 years, which was diagnosed as angioneuroma of the hands. In April, 1907, a swelling formed on the dorsum of the right hand towards the radial side. It was situated over the first and second metacarpal bones and appeared to surround more particularly the extensor tendon of the index finger. The growth was always extremely painful to the touch and sometimes gave her pain even when the part was at rest. The skin over the tumour was hotter than in other parts of the hand, at the centre it was red, but there was a dark bluish discolouration around the circumference. The swelling increased rapidly while she was under observation for a few days previous to operation. A mass of nævoid tissue of about the size of half a crown was excised through a T-shaped incision. Dr. Hebb made the following report on the specimen: "It consists of fibrous and adipose tissue in which are numerous blood-vessels, the arterial walls being extremely thick." The left hand had been similarly affected in January, 1907, when the girl was operated upon by my colleague, Mr. Arthur Evans. In January, 1908, she reappeared at the hospital, as the angiomatous condition had re-formed on both hands. The striking feature of her case was the extreme tenderness, and the parts were so sore that it was impossible to examine them properly. Further, the swellings were hard and appeared hotter to the touch than elsewhere. An operation was undertaken by Mr. E. Rock Carling and a considerable mass of nævoid tissue was dissected from the extensor tendons over which it had spread.

Now in the case of acquired painful lipoma, and in the nævoid condition just described, in which fat was present, we have certain conditions in common—namely, their excessive vascularity, the size and thickness of the vessels, and their extreme tenderness. It is difficult to account for the tenderness. It may be due to irritation of the nervi vasorum. Certainly no nerve fibres or endings could be discovered in the substance of the growths. Whether the acquired diffuse form is due to fatty degeneration of nævoid tissue is not proven, but this possibility should be borne in mind.

We now pass on to certain clinical points. Without careful observation the swellings due to acquired painful diffuse lipoma may partially fill up the arches of the feet, so that the condition can be mistaken for flat foot; but in all the cases I have seen, numbering now five, the tumours have always been between the inner edge of the sole of the foot and the internal malleolus, and have not extended further forward than the anterior part of the sustentaculum tali. In no case have I seen them over the scaphoid or internal cuneiform bone. The striking features about them are their slow growth and their indolence, their extreme tenderness, and their vascularity when cut into. It is also noticeable that any pressure, whether arising from an irregularity on the inside of the boot or from the employment of a "flat-foot" pad, renders the patient completely unable to get about on account of the pain. Finally, on removal, they do not, as far as I know, recur, and in this respect are entirely different from the congenital diffuse lipoma.

Harley-street, W.

SANITATION IN A TERRITORIAL CAMP.

By J. S. WARRACK, M.A., M.D. Aberd., D.P.H. Cantab.,

CAPTAIN, R.A.M.C. (T.); SURGEON-CAPTAIN, A.M.R. (O.); ASSISTANT MEDICAL OFFICER, PORT OF LONDON SANITARY AUTHORITY.

The following account gives some idea of the methods of sanitation and sanitary training adopted at the Kent Brigade training at Walmer from July 25th to August 8th, 1908.

On appointment as sanitary adviser to the senior medical officer of the brigade I went over the ground and thought out the best means whereby the sanitation could be carried out so far as possible on the same lines as in the regular forces. I found that the methods used in the Hampshire training and manœuvre area 1907 were most applicable. The troops, over 2000 in number, consisting of four battalions of infantry, a battalion of cyclists, two field ambulances, Army Service Corps, and a cadet battalion (during the second week) were camped on the slope of a hill facing the sea. The formation of the hill was of chalk on the upper two-thirds and of loam on the lower one-third. The camp was divided into two parts by a public street kerbed and channelled. There were open fields to the south and to the north a plantation of trees. On my arrival I found that the camp had been pitched and that deep latrines had been dug on the flanks, which were already foul. The kitchens and the ablution benches adjoined the main street. There were no destructors and no urinals and the refuse tubs were uncovered. The latrines on the south flank were well away from the tents. Those on the north flank were in undesirably close proximity to the tents and the stores and to a public footpath. There was really no other place where they could have been dug. Water was laid on in iron pipes and standpipes were to be found in various convenient positions. It was obvious then that dirty water could be disposed of separately from excreta.

A detailed inspection was made on July 26th. Arrangements were made for inspecting all food supplies, dry canteens, kitchens, horse lines, and the sanitary accommodation generally, and for lectures to be given on sanitation to the troops. An official inspection was made every morning by the senior medical officer and myself, and I paid frequent visits to all parts of the camp at uncertain hours during the first few days.

Food inspection.—The meat supplied throughout was good. On three occasions meat was rejected: (1) a carcass of frozen mutton, which showed signs of recent pleurisy in the pleural cavities; (2) a forequarter of frozen meat which was tainted; and (3) a forequarter of frozen meat supplied instead of home-killed meat. The bread supplied was of good quality. Dry canteens were inspected and all food and comestibles ordered to be covered with muslin or wire-netting. Perishable food supplies were ordered to be kept in cool places and covered up. The cooking arrangements varied from field ovens to portable kitchens, stoves, and boilers. No two units were alike in their cooking arrangements. Messing as regards the battalions was in tents. This I consider to be undesirable, it fouls the ground and attracts flies. There is much unnecessary waste. A large proportion of the contents of the refuse tubs were found to consist of bread, butter, and cooked meat. There is no accommodation in tents for the keeping of rations nor for washing up. The field ambulances and the cadet battalion messed in marquees; their ground was always free from food refuse and was much easier to keep clean. If attention is given to detail men can be as easily fed in messes in marquees as on transports. They are more comfortable. The ground remains clean and labour is saved in the picking up of scraps and in the washing up afterwards.

Disposal of refuse.—Large tubs or barrels were supplied by a contractor who removed the food refuse periodically. He was required to supply wooden covers for the tubs. This, after a little pressure, he did. The lids, however, were not invariably to be found on the tubs.

Dry refuse.—On my suggestion each unit in the camp built a destructor. These were circular structures 3 feet in height and 2 feet across, with openings at the bottom to admit air. They were made of sods strengthened by wood battens, or of bricks puddled with clay. The plan was shown to the pioneers, and it was left to their ingenuity to carry it out in detail. These destructors worked well; dry rubbish, tins, &c., were burnt up, and they lasted all the camp. They were most satisfactory.

and cyanosis; dyspnœa was still present. At no time has clubbing of the fingers been noticed. During the past winter the patient has been under medical care at Dresden and effervescent carbon-dioxide baths and moderate exercises were prescribed. On Feb. 3rd of the present year the patient was again seen by us. He is quite free from all dyspnœa even on great exertion, and he has completely regained his weight. The condition of the chest is but little altered from what was observed on June 29th, 1907, the difference being that the dulness previously observed is now a little lower and the upper right chest is a little more resonant than normal. The obscurity of the cardiac dulness is maintained.

Radiographic examination.—This was carried out by Mr. R. Higham Cooper on March 3rd, 1908. The shadow shown by the heart was normal in extent and position, and the diaphragm reached to the level of the fifth rib in the nipple line on both sides during expiration; posteriorly during expiration the dome of the diaphragm forming the upper limit of the liver reached as high as the seventh rib in the scapular line.

Comments.—In reviewing the illness and the subsequent developments it appears to us that on May 2nd, 1907, an embolus was dislodged from one of the veins of the lower extremities or a thrombus[1] was dislodged from the pulmonary artery and was driven into the lower division of the right pulmonary artery—i.e., into the branch supplying the middle and lower lobes of the right lung. These two lobes became atelectatic and the space formerly occupied by them when fully expanded was filled up by the ascent of the liver and right half of the diaphragm, and also probably by compensatory emphysema of the left lung in the direction of the right chest, accompanied by the upward dislocation of the stomach and left half of the diaphragm. The area of cardiac dulness was, especially towards the left, obscured by the compensatory emphysema of the left lung, the heart itself being little altered, if at all, so far as clinical examination could determine, in its normal position. We believe that the upper lobe of the right lung is undergoing compensatory hypertrophy and we anticipate that in the course of time it will be able completely to occupy the space formerly filled by the three lobes of the right lung if it has not already almost done so, as the diaphragm as shown by the x rays now during expiration reaches the height of the fifth rib in the right nipple line, the level reached in a normal individual, though probably the normal level in our patient owing to his original emphysema is lower. This view is supported by the observation by one of us that in a patient who died from an acute illness the left lung consisted almost entirely of the upper lobe of the definitive lung, the lower one being represented by an attenuated mass of atelectatic lung substance with a complete but small system of bronchial tubes, the whole not being much larger than a hen's egg.

A blood examination made 19 days after the accident of May 2nd, 1907, showed 5,687,500 red corpuscles and 9375 white corpuscles per cubic millimetre; the relative proportions of the latter were normal; the hæmoglobin amounted to more than 100 per cent., from which it may be surmised that the hæmoglobin had increased beyond the normal limits in response to a reduction of the normal lung substance

We are unable to find any reference to any account of survival after such an extensive obliteration of lung substance by an embolus or thrombus. Cohn refers in the section of his work[2] dealing with embolus of the pulmonary artery to two cases (Cases 1 and 14) in which *at the post-mortem examination* old or partly old clots were found in the pulmonary artery, but there is *no information* which would lead us to understand that the actual deposit of the embolus had taken place and had been clinically observed at a time as long as 11 months previously, as in our case. Our case now shows no signs of distress in breathing and in fact he is quite well. We believe that the reason why in this case the heart has not been dislocated into the right chest, as happens so often in tuberculosis and fibrosis of the right lung, is to be found in the possibility that the diaphragm, unaltered and unhampered by inflammation as it was, was readily able to yield and so allow the liver and the left lung instead of the heart to fill the place of the collapsed lung, or it may b that the mediastinal structures in our patient are more firn and less capable of actual displacement.

NOTES ON THE THERAPEUTIC APPLICATION OF STOCK VACCINES IN THE TREATMENT OF BACTERIAL INFECTIONS.

By JOHN MATTHEWS, B.A., B.C. CANTAB.,
ASSISTANT IN THE DEPARTMENT OF THERAPEUTIC INOCULATION, ST. MARY'S HOSPITAL, LONDON.

OPSONINS is the name given by Wright and Douglas t those protective substances in the blood serum in the absenc of which leucocytes are only capable of phagocytosis in very limited degree. As immunity to bacterial infection depends largely on phagocytosis opsonins play an extremel important part in producing immunity. It has been show that after recovering from a microbic infection the proportio of protective substances, or opsonins, in the patient's serun connected with that particular infection is higher, to a greate or less extent, than in the serum of a normal health individual. It has also been shown that if an inoculation o killed microbes be made into a normal individual th proportion of opsonins in his serum will rise as compare with the serum of a normal individual not so inoculated.

In the vast majority of microbic infections the physiological mechanism of immunity reacts so quickly to th infection that an adequate supply of protective substances i brought to the site of infection and the phagocytes ar enabled to cope with the microbes. Such an infection wil rarely be attended with symptoms either objective o subjective, and will therefore be unnoticed. In cases whic are not so aborted and which therefore become noticeable a local or general infections, either the infection has been to virulent for the normal mechanism to cope with or for some reason, such, for example, as great exhaustion due t exposure or local injury, the normal mechanism for th production of immunity is deficient. Therapeutic inoculatio supplies a method of artificially producing immunity and th object of this paper is to indicate the potentialities and limitations of therapeutic inoculation in the treatment o microbic infections, generally with the assistance given by the frequent estimation of the opsonic index but mor especially without the aid derived from the opsonic index.

The opsonic index is the expression of the measure of the phagocytic power produced in a sample of washed leucocytes by the serum of the individual in question, as compared with the phagocytic power induced in a similar sample of leucocytes by the serum of one or more healthy individuals. This latter power is taken as unity, and the index of an infected individual is expressed as a fraction of unity, above or below unity according to the greater or less quantity of protective substances in the infected serum, as compared with the normal serum. The opsonic index then is the measure of the resisting power, as comprised in phagocytosis, of a serum, against the microbe in question.

A *vaccine* is a killed bacterial culture suspended in sterilised normal saline solution, to which lysol to the strength of ¼ per cent. or carbolic acid to the strength of ½ per cent. has been added. Vaccines are accurately standardised by mixing together definite quantities of vaccine and normal human blood of known corpuscular content. Smears are made of the mixture, are dried, fixed and stained, and the numbers of red cells and microbes in many successive fields of the microscope are counted. An estimation of the number of microbes in each cubic centimetre of vaccine is then possible. The cultures are killed by immersion for one hour in a water bath at 60° C., and the sterility having been demonstrated by culture methods a suitable dilution for use is made in rubber-capped sterile bottles for laboratory and hospital use, and in sealed glass sterilised capsules, containing slightly more than one cubic centimetre, for general use.

The effect of vaccines on the blood.—The injection of a dose of vaccine into a healthy normal individual produces either (1) an immediate rise in the protective substances, as indicated by the opsonic index; (2) a fall of longer or shorter duration, followed by a rise up to or above normal, in

OBSERVATIONS ON A CASE OF HUNTINGTON'S CHOREA.

BY J. J. W. EVANS, M.R.C.S. ENG., L.R.C.P. LOND.,
LATE HOUSE PHYSICIAN TO WESTMINSTER HOSPITAL.

As is well known, the diagnosis of the above rare disease rests upon the following facts: (1) Choreic movements which are of a hereditary nature; (2) difficulty of articulation leading to a slurring character of speech; (3) progressive dementia and emaciation; and (4) exaggeration of the deep reflexes. All the above symptoms make their appearance during the middle period of life, most frequently between the ages of 30 and 40 years. A curious fact about this case of Huntington's chorea which came under my observation quite recently was that the symptoms increased at the time of the menopause, and on this account the story may afford some interesting matter.

On June 3rd, 1907, a woman, aged 41 years, was admitted into the Westminster Hospital under the care of Dr. R. G. He[illegible]. Until 1902 she had always enjoyed good health; in that year, however, she began to develop spasmodic movements of the face and arms. Soon afterwards the speech became affected, rendering articulation progressively more difficult. Her character also changed and from being bright and cheerful she became moody and indifferent to her surroundings. Menstruation was regularly performed until September, 1906, when the function suddenly ceased, and at this time all the symptoms became extraordinarily worse. The moodiness developed into definite dementia; so acute became the movements that they prevented the patient alike from feeding herself and from walking. Simultaneously with this state of affairs progressive dysphagia made its appearance, while she became more and more emaciated in spite of an abnormally large appetite. In this connexion I may mention that at the time of admission into the hospital she was unable to protrude the tongue. At this time also constipation and insomnia made their appearance and continued troublesome during the remainder of her life. All these combined circumstances rendered the patient almost beyond recognition.

The movements which were present in all the limbs were most marked in the arms; they were of a continuous whirling character, too quick and jerky for athetosis, and they ceased during sleep. There were no fibrillary tremors of the muscles. The deep reflexes were not markedly exaggerated, but the plantar reflexes on both sides were extensor in type. The pupils were normal in reaction and in size. Sensation was unimpaired, and on examination of the cerebro-spinal fluid nothing abnormal was discovered. The cardio-vascular, respiratory, and urogenital systems presented no abnormality. Towards the end of June, 1907, there was repeated incontinence of urine and fæces and on June 22nd a nasal discharge developed. About this time the patient become noisy and insomnia became worse, necessitating the administration of drugs. On the 29th the temperature, which had up to this time remained normal, suddenly rose to 102·4° F. and continued high and remittent until on July 2nd it reached 105° and the patient died. During this febrile period the breathing was very rapid but there were no physical signs to account for the condition.

The family history is valuable and interesting as the grandfather and father of the patient were both similarly affected, but to a less degree physically, as, unlike the patient, they were never bedridden, both ending their days in lunatic asylums. The patient's brother and his children have shown no signs of the disease. The grandfather, it was said, was at some distant time bitten by a mad dog, and although actual evidence of this is not clear I think it should be mentioned as a possible explanation of his mental condition.

A post-mortem examination was performed 27 hours after death. The body was emaciated and rigor mortis was present. On opening the skull the dura mater was found to be everywhere thicker than normal; its inner surface was red and injected, and from it could be separated a delicate membranous exudate. There were much œdema of the arachnoid mater and excess of cerebro-spinal fluid. There was slight adhesion between the mesial surfaces of the frontal lobes. The brain weighed 40 ounces; its substance was soft and flabby and the cortical grey matter was thin; the pia mater was not thickened and could be easily stripped from the surface of the cerebrum. The lungs showed scattered broncho-pneumonic patches throughout both lower lobes; there was a small amount of fibrinous lymph in each pleural cavity. The remaining viscera showed no changes of pathological importance. Death resulted from pneumonia.

Microscopically the exudate upon the inner surface of the dura mater was seen to consist of blood-stained fibrin. The cortical pyramidal cells of the cerebrum had the appearance of shrinkage and there was a clear space around them. I can find no trace of granules which are described by French authors around these cells. No other changes have been detected.

I wish to offer my sincere thanks to Dr. Hebb and Dr. J. M. Bernstein for their valuable assistance.

Reviews and Notices of Books.

Surgery, its Principles and Practice. By Various Authors. Edited by WILLIAM WILLIAMS KEEN, M.D., LL.D., Emeritus Professor of the Principles of Surgery and of Clinical Surgery, Jefferson Medical College, Philadelphia. Vol. III., with 562 text illustrations and 10 coloured plates. London and Philadelphia: W. B. Saunders Co. 1908. Pp. 1132. Price 30s. net.

A GLANCE at the list of the contributors to the third volume of this System of Surgery is sufficient to show the high character of the work. All the names are those of well-known surgeons and each has dealt with that subject with which he is best acquainted.

Dr. Harvey Cushing of Baltimore has supplied the section on the Surgery of the Head. It is excellently written and fully illustrated. The author might have explained that the reason why in fractures of the skull very little callus is formed is that there is complete absence of movement. The moving of the fragments is the main cause of the formation of callus and the callus formed is directly proportional to the amount of movement. Dr. Cushing mentions that he has frequently replaced a trephine button of bone after boiling it and he has never seen it fail to heal in place; it is well known that a trephine button can be replaced with safety, but we do not remember to have seen hitherto any case mentioned in which the button was boiled first. Dr. Cushing discusses very fully the question of the best method of draining a hydrocephalus. He determines whether the foramen of Magendie is open by puncturing simultaneously the ventricle and in the lumbar region, and if the tension levels of the two are the same the foramen of Magendie must be open. The analyses of the two specimens of fluid withdrawn should also be identical. In such a case he has practised subperitoneal drainage in the following manner. A few days after the punctures a laparotomy is performed, the posterior layer of peritoneum to the left of the rectum is split, and the body of the fifth lumbar vertebra is exposed; the bone is trephined by means of a very small calibre trephine and a small cannula is inserted. Then a laminectomy is performed, the subarachnoid space is opened, the strands of the cauda equina are separated, and another cannula is [illegible] pushed forward until the two [illegible]. Both [illegible] closed and drainage of the cerebro-spinal fluid [illegible] first into the peritoneum, but later only into the [illegible] peritoneal space. Dr. Cushing tells [illegible] out this method in 12 cases with a [illegible] of success. As this is [illegible] novel and interesting pr[illegible] we should have [illegible] details of the cases [illegible] has been [illegible] Intracerebral hæmorrh[illegible] attention hitherto, but [illegible] possible to reliev[illegible] blood into the [illegible] much larger class of case than we considered in connexion ith Diagram 1. The majority of cases which the immunisator is called upon to treat are comprised in chronic or cute, strictly localised processes. In some the resistance of he circulating blood is actually above normal; in most it is, owever, below normal, and is likely to be variable. In other ords, the state of resistance of the circulating blood may ot necessarily have an immediate effect upon the local nfection. Hence, a temporary negative phase, if followed y a more or less prolonged positive phase, will be of no onsequence. The practical result is that by giving such a lose that a small negative phase is produced we obtain a ositive phase that will probably last seven or eight days, nd so the injections may be interspaced by a period of some 0 or 12, or even more, days. In this class of case we may herefore consider the result depicted in Diagram 2, an "ideal curve."

In most cases the negative phase should not last longer han 24 hours. The temperature will be no guide, for most of such cases will be apyrexial, and the indications as to dosage, apart from opsonic indices, will be mainly local. They will be objective and subjective. The subjective symptoms will be some or all of the following: malaise and increased tenderness and pain at the site of the lesion and in bladder cases increased frequency of micturition. Objectively there will be some or all of the following: increase of discharge, swelling, and congestion, and in the case of acne, and such like more or less generalised local infections, an increase in the number of foci of infection, and in bladder cases perhaps more cloudiness due to increased activity of the infective microbe. In short, during a negative phase an increase of those signs and symptoms due to the infection under consideration will be noticed. Such increase should only be noticeable for not more than 24 hours, and subsequently an amelioration should take place.

It is hardly necessary to point out that should any of the symptoms above mentioned be severe it would be advisable to return to smaller doses—that is to say, an endeavour should be made to proceed as in those cases in which Diagram 1 was said to be an "ideal curve." Necessarily inoculations will be more frequent.

In the case of tuberculous lymphatic glands and suppurating acne, which cases are probably the most numerous that one is called upon to treat, *in which results* such as depicted in Diagram 2 are aimed at, a slight subjective tenderness in the glands or an increase in the number of comedones respectively would not be of importance if lasting for not more than 24 hours, provided they were followed by a positive phase that lasted a week, more or less.

We now come to the consideration of the result of an inoculation as depicted in Diagram 3. With possibly one exception such a result is wholly bad. *It is disastrous* in acute general infections and it is at the best useless in chronic or acute local infections. The one exception is the case of a furuncle in such a condition of maturity that absorption without suppuration is unlikely *to occur*. In such a case it may be desirable to give such a dose of staphylococcus vaccine that a marked *negative* phase is produced during which rapid maturation with breaking down and subsequent *evacuation* of the abscess occurs.

The foregoing general considerations *rest* on the experience gained from the results of therapeutic inoculation as carried out at St. Mary's Hospital, where the majority of the inoculations are controlled by a varying number of opsonic indices. Nevertheless it is realised that in a vast number of cases the estimation of opsonic indices must be out of the question, and if it be a choice between therapeutic inoculation without opsonic indices or no inoculation at all, then therapeutic inoculation undertaken without indices most certainly is indicated. Moreover, we have now the accumulated experience of several years to generalise upon—an experience which takes cognisance of upwards of 15,000 opsonic estimations per year, carried out by the staff of the Department of Therapeutic Inoculation at St. Mary's Hospital. As the result of this experience the practice of vaccine therapy *is becoming* in certain directions more crystallised. Though we are more inclined to dispense with opsonic indices in the treatment of staphylococcal lesions than in any others, vaccine therapy without opsonic indices *need* not be confined to the treatment of such lesions, but may be applied to some cases of tuberculous, streptococcal, and gonococcal lesions as well as to the preventive inoculation of typhoid fever. For this purpose vaccines are prepared, standardised, and put up in bulbs of a little over one cubic centimetre each at St. Mary's Hospital and are obtainable through Messrs. Parke, Davis, and Co. These vaccines are precisely the same as are regularly used at St. Mary's. It is to be understood that the following statements are the outcome of the experience derived from the treatment of a large number of patients in hospital and in private, treatment which has almost invariably been controlled by frequent estimations of the opsonic index, and the writer in no way relinquishes the conviction that the best use of bacterial vaccines will always be made when the effects of each dose are ascertained by means of the opsonic index.

Having thus briefly considered the general effect of the inoculation of bacterial vaccines, it is advisable to pass to the consideration of applying the principles as above sketched out to the treatment of individual cases, or classes of case, and this can best be done under two main headings: (1) Diagnosis of the microbe at fault, its isolation and culture, and the preparation and standardisation of a vaccine; and (2) the estimation of the amount constituting a correct dose and the determination of the correct period that should elapse before re-inoculation.

1. For the complete conception of *bacteriology indicated* in the above subheading standard works on the subject must be consulted. Here it is only necessary to point out the elementary factors to be considered. From clinical experience many common lesions are always associated with certain *micro-organisms* and where such a comparative certainty exists it is sufficient to obtain the appropriate vaccine and proceed with inoculation. Such common diseases may be tabulated as follows, though no completeness is aimed at:—Staphylococci are mostly concerned in furunculosis and carbuncle, osteomyelitis, sycosis, and suppurating acne. Frequently in eczema and whitlow and occasionally in infective endocarditis and septicæmias. Streptococci are mostly concerned in erysipelas, puerperal septicæmia, septic endocarditis, lymphangitis, and most forms of cellulitis. The tubercle bacillus is concerned in many chronic local joint, glandular, and osseous swellings, and many skin lesions, besides phthisis, tuberculous peritonitis, and frequently in infections of the genito-urinary system. Thus in many lesions met with in everyday practice experience tells us, without precise bacteriological procedure, what is the probable causal microbe.

A few details as to the technique carried out where the diagnosis is not obvious may be indicated. Any discharge from the lesion can be directly examined by an ordinary smear preparation, stained either by a simple basic stain or by Gram's method. If more than one organism be present an endeavour must be made to determine which is the immediate pathogenic agent. Thus a mixture of staphylococcus and streptococcus usually leads one to the conclusion that the streptococcus is the causal agent of the lesion; should, however, an exhibition of streptococcus vaccine not be followed by amelioration one would then give staphylococcus vaccine or a mixture of *both*. Where, however, it is possible to have recourse to opsonic indices the question may be settled *conclusively*. If the index be normal to the staphylococcus isolated from the *lesion and abnormal to the streptococcus* the latter is certainly wholly or mostly responsible for the lesion. A septic endocarditis or other septicæmia can, in the absence of any obvious primary or secondary lesion, only be with certainty diagnosed by making a blood culture. To do this about 10 cubic centimetres of blood are taken with all aseptic precautions from a vein, usually and preferably the median basilic; *about two cubic* centimetres of blood are directly introduced into each of four tubes of sterile broth. One cubic centimetre may be introduced into a sterile flask of peptone water if typhoid fever, paratyphoid or an infection due to a bacillus of the colon group, is suspected, and a *portion* may be spread on to the *surface of* an agar slope. If the organism be present in the blood it will in all probability grow in one of the media mentioned above. Subcultures are made and a vaccine is elaborated. Such *measures*, however, as a blood culture can only be carried out satisfactorily by a practised bacteriologist.

Apart from blood infections which may be diagnosed by means of blood cultures, many lesions may present themselves for *treatment* the cause of which is obscure. In such the opsonic index is of the *greatest* value, but it is beyond the embryology, especially that of Hubrecht on tarsius spectrum (lemur), has thrown a great deal of light on many vexed problems, yet our knowledge of the very early stages of the development of the human ovum itself is excessively meagre and it is fortunate that the present specimens should have fallen into the hands of such accomplished investigators as Dr. Teacher and Dr. Bryce. The problems in human embryology which are possibly of most general interest are those concerned with the early implantation of the ovum, the development of the placenta in its most primitive form, the development of the amnion, including the vexed question of the inversion of the germinal layers, and the problem which we may consider to be determined finally by the present specimen of the origin of the plasmodial investment of the villi, or the syncytium.

In a consideration of the different stages of development of the human ovum obviously the greatest importance must be assigned to a correct determination of the ages of the different ova which have been described. This has usually been determined arbitrarily by the so-called convention of His who reckons the interval of time which elapses between the date on which the first omitted period should have commenced and the termination of the pregnancy as the age of the ovum. The fallacies likely to arise from the use of such a formula are obvious, and the authors of this monograph have rejected this method and from a determination of the probable age of their own specimen, a review of the other recorded cases of early human ova, and a consideration of the known facts of comparative embryology have arranged a chronological table in which in many instances the estimated ages of the various early ova recorded differ very markedly from those assigned to them by their original describers. In the present case very precise and trustworthy data were obtainable and the authors conclude from a consideration of these that the ovum was about from 13 to 14 days old. In arriving at this figure they have allowed 24 hours as the time likely to have elapsed between insemination and fertilisation and 24 hours for the occurrence of the abortion.

From a careful consideration of the known facts and taking the estimated age of the present ovum as a basis on which to work, they conclude that it is the earliest human ovum hitherto described in the literature, and that Peters' ovum which he considers as only three or four days old is in reality from 13½ to 14½ days old. In the same way they have assigned ages to all the other human ova of which the details are recorded with sufficient accuracy, with the result that they arrive at a series of ova of gradually increasing age, the estimated ages of which correspond much more accurately to the facts determined by comparative embryology and to their own varying degrees of development than they do on the assumption that their ages are such as have been imputed to them previously by the various authorities who placed them on record. No doubt this table will meet with a considerable degree of adverse criticism from the various gentlemen the accuracy of whose deductions is in many instances impugned, but for our part after a careful consideration of the data as set out by the authors we are inclined to agree with their estimate of the age of their own ovum and of the others which have been described. If the contention be admitted as true that this is the earliest human ovum which has been met with hitherto, then its interest is obviously very great, and it throws a great deal of light on several vexed problems. For example, it shows a condition of the human blastocyst quite unsuspected, since its walls are almost entirely plasmodial, with the exception of a thin cellular layer of trophoblast, the so-called cyto-trophoblast forming the innermost lining of the blastocyst. Unfortunately, the early embryonic rudiment has been displaced and torn but the conclusions of the authors seem to us justified—namely, that the larger of the two vesicles present in the interior of the blastocyst is in reality an amnio-embryonic cavity in which there is as yet no distinction between amniotic and embryonic ectoderm, an earlier stage therefore to that shown in Peters' ovum, in which these two layers are already differentiated. In the human subject probably, as in tarsius the amnio-embryonic cavity is excavated in the interior of the so-called embryonic cell mass and the floor of the cavity at first concave and therefore apparently inverted becomes the embryonic plate while the roof becomes the amnion. Another interesting fact which the study of this early ovum has demonstrated is that the early mesoblast entirely fills the blastocyst and the extra-embryonic cœlom already present in Peters' ovum appears to be formed by a splitting of this mesoblast.

Much light has been thrown on the process of the imbedding of the early human ovum in the uterus by the study of this important process in the lower animals and it seems likely that the process in man resembles very closely that seen in the case of the guinea-pig. The authors consider the exact process to be as follows: the early blastocyst, still of very small size, comes to rest on a depression in the uterine mucous membrane, destroys the surface epithelium and, continuing its destructive activity, passes into the space in the decidua which has thus been produced. Necrosis followed by solution of a considerable mass of the endometrium follows and in this way the large implantation cavity is formed, the development of the decidua beginning immediately after the destruction of the epithelium. The ovum now becomes surrounded by a thick covering layer of trophoblast, by which it ultimately becomes fixed to the uterine decidua. The idea that the uterine epithelium is necessary for the production of the plasmodial layer of the trophoblast has already been disproved by Catherine van Tussenbroek in her description of a case of ovarian pregnancy, and the second specimen described in this monograph seems to show that it is possible for an ovum to become imbedded in the stroma of the ovary, and therefore it cannot be the follicular epithelium of the Graafian follicle which is converted into the plasmodium; the proof, then, now seems complete that the latter is of entirely fœtal origin.

The importance of these two specimens can hardly be overestimated, and we congratulate the authors on their good fortune in obtaining the material and on the most excellent use which they have made of their exceptional opportunity.

The Treatment of Gonorrhœa in the Male. By CHARLES A. LEEDHAM-GREEN, M.B. Birm., F.R.C.S. Eng.; Surgeon to the Queen's Hospital, Birmingham; Surgeon to the Birmingham and Midland Hospital for Children; Consulting Surgeon to the Birmingham General Dispensary. Second edition. London: Baillière, Tindall, and Cox. 1908. Pp. 160. Price 5*s.* net.

THE serious results of gonorrhœa are at the present day more fully recognised than they were a few years ago, yet even now the public consider that an attack of gonorrhœa is of little moment. It is essential to cure a gonorrhœa as soon as possible and Mr. Leedham-Green's book is a very trustworthy guide. He insists that in order to treat the disease rationally the surgeon must determine (*a*) whether it is a case of true gonorrhœa; (*b*) the stage of the disorder; (*c*) the extent to which the mucous membrane is affected; and (*d*) the presence or absence of complications. He advises that the patient should rest in bed during the early stages of the disease, but it is very difficult to persuade the average patient that so much rest is advisable. For internal treatment he speaks highly of a combination of sandal-wood oil has lasted without relapse for upwards of nine months and bids fair to be permanent.

Some cases of tuberculous infection will provide a certain amount of objective and possibly subjective signs by means of which guidance is afforded in dosage. Thus a tuberculous lymphatic gland may be rendered slightly tender to the touch, or even slightly painful by a certain dose. If such pain and tenderness last less than 24 hours it may be concluded that the dose was appropriate. Similarly a tuberculous joint infection may by increased pain and tenderness, with or without exercise, afford evidence as to the appropriateness of the previous dose.

In the case of streptococcus apart from acute general infections, the majority of the lesions to be treated will be local cellulitis, lymphangitis, and erysipelas, and secondary infections of tuberculous sinuses and lupus vulgaris. The local primary infections have to be approached with caution, and small doses only can be given. The clinical results are, however, so rapid as to afford very material evidence as to the appropriateness or otherwise of the antecedent inoculations. In the secondary streptococcal infections, notably those connected with tuberculous processes, the condition is as a rule, very chronic and sluggish. Larger doses of vaccine are borne without much negative phase, and indeed a slight negative phase may be not contra-indicated, as it may produce a flushing of the lesion with blood and increased exudation of lymph. The progress in these cases is, however, slow, and treatment may have to extend over several months. The secondary infection of lupus with streptococcus often obscures the clinical picture, and care must be exercised that a streptococcal infection be not mistaken for an exacerbation of the tuberculous process. Again, in gonococcal lesions, clinical signs afford valuable guidance. At St. Mary's Hospital the majority of our cases have been arthritic and in these an excessive dose is indicated by increased pain and stiffness with possibly a general malaise.

Some cases of urethritis have been treated with varying results. An autogenous vaccine, that is, one prepared from the patient's own organism, sometimes gives very good results. The negative phase is here indicated by an increase in the gleet, and if this lasts but one day a good result may be expected from the antecedent dose. With regard to gonococcus a marked difference occurs in the case of different vaccines. Thus a vaccine which we have been using for some months at St. Mary's Hospital gives good results in doses of from 2½ to 10 millions, other vaccines may require as a dose 40, 50, or possibly more millions. A recently isolated organism from a gleet gave no appreciable negative phase with an initial dose of 20 millions, and, indeed, only a slight fall towards normal was indicated opsonically, the index having been previously raised by the exhibition of a small dose of stock vaccine. By the fifth day, however, the resistance was nearly doubled and no organisms were found in the discharge which had previously abounded with gonococci. Examples might be multiplied indefinitely but those given above will suffice to indicate the lines to be proceeded upon in those cases in which clinical signs afford evidence as to the appropriateness or otherwise of each individual dose of vaccine.

The essential points in this class of case may be summarised thus. A dose of vaccine may be considered as appropriate when any negative phase, as indicated by objective or subjective signs, is only temporary and is followed by a longer or shorter period of improvement. Up to a certain point the period of improvement is proportional to the duration of the negative phase, but a point is soon reached when no improvement beyond the pre-existing condition is obtained. Beyond this point then a dose may be considered to be excessive. Conversely, if a short period of improvement with no signs of an intervening negative phase occur the succeeding dose of vaccine may be cautiously increased. As regards staphylococci the only exception to the above broadly stated rule would appear to be infective endocarditis and septicæmia, which are occasionally caused by staphylococcus. In such cases it would hardly be proposed that opsonic indices should be dispensed with, but were these latter out of the question it is obvious that extremely small doses should be given, though it might be advisable to repeat them with more than usual frequency, even to daily doses. Practically the only guide in such cases beyond the conditions of any local lesion that might be present would be the temperature. This, however, has been in some cases very valuable, indicating fairly accurately the state of resistance of the blood. Roughly, the temperature rises with a lowering of opsonic index, and *vice versâ*.

We now come to the consideration of the second class of case—namely, that class in which no objective signs immediately follow the exhibition of an appropriate dose of suitable vaccine. As an example of this class of case a tuberculous lymphatic gland was instanced. While it is true that in some cases a suitable dose of vaccine may be followed by slightly increased tenderness or even pain at the lesion, it is certain also that many, if not the majority, of these cases do not afford this evidence. Examples of negative phases that have been prolonged over several days as indicated by the opsonic index might be given in which no evidence as to increased tenderness or pain could be elicited. Again, in cases where two or more organisms are in question, the symptoms due to each several variety of microbe may not be obvious. In such it may be difficult to determine the value of any individual dose; it should be noted, however, that cases involving more than one organism are on the whole rare.

A tuberculous lymphatic gland may be taken as the most frequent lesion to be treated, in which clinical signs afford but little guidance. From week to week no great difference may be observable, and a long period may elapse even when resolution, as the result of appropriate doses of tuberculin, is occurring before the improvement is obvious, a period at least long enough to allow of several doses of tuberculin to be given. Hence it follows that there is no evidence as to which of several possibly varying doses of tuberculin given has been the correct one.

Not having the knowledge gained by constant estimations of the opsonic index recourse must be had to previous experience of similar cases. Before considering the application of this experience to particular cases it is advisable to differentiate between strictly local and more generalised cases of tuberculous infection. A much larger dose may be given in a strictly local case than in a more generalised case. Thus in the case of a robust adult presenting himself with a tuberculous lymphatic gland of the neck it would be good practice to give 1-15000th to 1-10000th of a milligramme of T.R. as an initial dose. If however, there were any involvement of the lung 1-30000th might be quite large enough a dose. The consideration of such lesions as pulmonary tuberculosis and tuberculous peritonitis must be superficial, however; suffice it to say that any doses larger than 1-30000th to 1-20000th must be given with extreme caution. A negative phase of even a few hours' duration may give opportunity for disastrous activity of the tubercle bacilli in such, cases and with no evidence of the existence or otherwise of auto-inoculation a dose which might be suitable one day might well be excessive the following day.

To return to such localised infections as tuberculous glands without any constitutional disturbance. It has been stated that in an adult an appropriate initial dose would be from 1-15000th to 1-10000th milligramme. Such a dose may be administered not more frequently than once every 10 days and may be raised gradually every third dose until 1-5000th to 1-4000th milligramme be reached. Usually it is unnecessary to proceed any higher and 1-4000th milligramme may be given for months with good effect. It is not suggested that every case can, however, stand such doses, but the exceptions will be few. Cases of lupus stand tuberculin well as a rule. Rarely have we occasion to give a dose as large as 1-2000th milligramme. It must be understood, however, that in the absence of the check afforded by opsonic indices any dose greater than 1-4000th milligramme of T.R. is dangerous, at least in the first six months of treatment. Cases of genito-urinary tuberculosis will not stand large doses of tuberculin as a rule, and 1-5000th should be regarded as a maximum. In children below the age of ten years the doses are smaller, though proportionately children take tuberculin well. A typical chart of the opsonic indices and doses of tuberculin is appended as an example (Fig. 2). The case was one treated in the ordinary routine of practice and the indices were not worked out with a view to the formation of a curve chart.

Note with regard to curve.—The dotted lines have been inserted to indicate the probable diagrammatic course of the resistance. It is to be noted that when any particular dose was ceasing to be the correct one the response was very rapid and short-lived.

Nowhere in the book does he state expressly the cause or treatment of cancer, but he suggests that cancer is brought about by unhygienic modes of living and that dietetic methods of treatment will help to remove it. We find some curious statements in the book. In speaking of the thyroid gland Dr. Bell says on p. 241: "To enable it to perform this duty [the destruction of poisonous substances in the blood] more efficiently, as one observer has stated, the blood performs two circuits through the thyroid before its return to the heart." We should like to know where this interesting fact is recorded and who observed it. In the introduction on p. 13 we are told that Metchnikoff states that in the intestine there are developed daily 28,000,000,000 of bacteria. On p. 190 Metchnikoff is again quoted, but now the number has risen to 128,000,000,000,000, or more than 4000 times as many. Perhaps in these high figures a few ciphers more or less make little difference.

School Hygiene and the Laws of Health. By CHARLES PORTER, M.D., B.Sc. Edin., M.R.C.P. Edin., of the Middle Temple, Barrister-at-Law. Second edition. London, New York, Bombay, and Calcutta: Longmans, Green, [illegible] 1908. Pp. 335. Price 3s. 6*d.*—*The Wonderful House that Jack Has: a Reader in Practical Physiology and Hygiene.* By COLUMBUS N. MILLARD, Supervisor of Grammar Grades, Buffalo Public Schools. New York: The Macmillan Company. 1908. Pp. 359. Price 3*s.*—*Ball Games and Breathing Exercises.* By ALICE R. JAMES. With Preface by HARRY CAMPBELL, M.D., B.S. Lond., F.R.C.P. Lond. London: Longmans, Green, and Co. 1908. Pp. 61. Price 1*s.* 6*d.*—This trio of books dealing with different branches of school hygiene may be conveniently considered together. The first and third of them are manuals of instruction addressed to teachers; the second, as its title suggests, is intended as a lesson-book for young children. We need say little about Dr. Porter's work, which was originally based on lectures to school teachers, save to record its second edition, for we reviewed it at length when it first appeared. We were then able to say that it was an admirable text-book in elementary physiology and hygiene for the instruction of school teachers, and a fresh acquaintance with it confirms our opinion. It deserves to become a standard text-book in a subject the importance of which has been so prominently endorsed by recent legislation. As was fitting, Dr. Porter has added a useful little chapter upon medical inspection of schools as it concerns the teacher, rightly laying stress upon the enormous assistance which he or she can afford to the school medical officer by sympathetic coöperation in his inspection work. We regret that Dr. Porter has not seen his way to add a chapter on punishments, a subject upon which his experience should prove of value. The next book is of a very different order. It is an attempt to familiarise children between their fifth and eighth years with the outstanding principles of physiology and hygiene. We think that Mr. Millard has made a mistake in his method. In *The Wonderful House that Jack Has* he has produced a book of the "my dear little children" order containing a number of pictures, some of which irresistibly recall that delightful ephemeron, *Wisdom While You Wait.* In his preface he states that most school physiology books are too full of technical terms and quotes to prove his point. In turn it is legitimate to ask him whether words like "preëstablished," "preëminent," "detrimental," "expectoration"—we pick at random from his pages—are quite suitable in talking to children of tender age, and whether they will profit by hearing about the treatment of adenoids, errors of refraction (including astigmatism) and their correction, the methods of detecting oleomargarine from butter, or of disinfecting a room after enteric fever. The author has, moreover, a habit of dropping into such sententious remarks as these: "But what about fish? How do these finny dwellers in the water world, which so many people greatly enjoy luring from their liquid home, help in our structure?" And again, "Who has not felt pity for Esau because he allowed his greed for pottage to lose him a commanding position and valuable estates? ...... Candy and rich desserts are the pottage most likely to lure away our precious inheritance." This strikes us as the way not to address a "Jack" of six, and however much it may be desirable to instil him with a hatred of tobacco it is surely not ingenuous to conclude a passage worthy of the royal "Counterblaste" with the statement that "we rarely, if ever, find one who does not regret having burned his money up in this way." But with all these faults Mr. Millard has written many pages which would form excellent lessons for little ones, especially those concerning food, ventilation, and breathing. We think, though, that he would have been better advised to adopt a style more suited to older children and to leave the infants to the oral instruction of their teachers. His text-book is altogether too ponderous [illegible] s. The third little book before us gives an [illegible] of an ingenious series of physical exercises performed with the help of indiarubber balls, which have been devised by Miss Alice James and have received the blessing of Dr. Harry Campbell. They aim at grace and lissomeness rather than hard and bulging muscles, and they should help to cultivate ambidexterity. So far as we can follow them from the figures and descriptions they are well adapted for the physical development of children and young women. It would be desirable for a teacher to see the exercises in practice before adopting them, and anyone desiring to do so is invited to attend an evening class at Northfield, 101-105, Stamford-hill. With such an introduction this little manual should prove of great service to gymnastic instructors and "games mistresses."

The Extra Pharmacopœia of Martindale and Westcott. Revised by W. HARRISON MARTINDALE, Ph.D., F.C.S., and W. WYNN WESTCOTT, M.B. Lond., D.P.H. Thirteenth edition. London: H. K. Lewis. 1908. Pp. 1164. Price 10*s.* 6*d.*—The authors are masters of the art of abstracting and of condensing the information scattered in literature. The only criticism, indeed, that is invited turns on the question as to whether the book is not after all overstocked with information, and yet it cannot fairly be said that the information throughout is without interest or value in some way or other to the medical man, pharmacist, and others. The advisability of including certain materials may be doubtful, while strictly they may not belong to the subject matter implied by the title of the work. There are sections, for example, on the analysis of milk and butter, on poisoning by certain gases, on mineral waters, health resorts, and so forth, which few, we imagine, would expect to find in a pharmacopœial work. The omission of these sections would have made room for further treatment of the more strictly pharmacological portions of the book. Nothing succeeds, however, like success, and the authors have doubtless very good reasons for including the treatment of what are after all collateral subjects. The book has now reached its thirteenth edition, the first issue having been published in 1883, and it is well known that its *clientèle* is a wide one and includes the members of different professions. The medical man, the analytical chemist, the pharmacist, the bacteriologist, and even the lawyer, commonly and rightly regard this work as a valuable and trustworthy source of reference. The copious references alone to the literature of pharmacology make a copy of the book well worth while possessing. This last edition includes a considerable amount of valuable new material, in proof of which mention need only be made of such subjects as the

To summarise the treatment of cases in which no immediate indication as to the appropriate dose is afforded by clinical signs, such cases being generally tuberculous, it may be stated thus. In generalised tubercle, as phthisis and tuberculous peritonitis, larger doses than 1-30000th milligramme are to be given with the greatest caution, and in advanced cases such a dose even may be excessive. In strictly localised infections in adults the doses may range from 1-15000th to 1-4000th milligramme. In children with similar infections the doses may range from 1-25000th to 1-6000th, according to age and physique.

The indications as to dosage have designedly been slightly more dogmatic in the class of cases in which clinical evidence as to the appropriateness or otherwise of dosage is scanty or non-existent. Any hurry to increase the dose is deprecated, it being better to give several possibly non-maximal doses than one large enough to produce a severe *negative phase* with a consequent set-back and the undoing of the good that may have pertained to many previous doses. The generalisation of the infection as opposed to strict localisation is the especial point to bear in mind. In the former small doses are to be insisted upon, for reasons given above.

In the preventive inoculation of typhoid fever previous experience can alone be relied on. Happily, this experience is extensive and the doses can be indicated with exactitude. 1000 million typhoid bacilli are administered and the patient is advised to rest, not necessarily in bed, for the rest of the day. A slight and varying amount of malaise, headache, and possibly joint pains will occur, but they usually pass off by the next day. Not less than ten days subsequent to the initial injection a dose of 2000 millions is given, and a similar sequence of symptoms may follow but is usually less marked than after the primary inoculation.

It is to be borne in mind that a high resistance in the circulating blood may not necessarily react in the direction of a cure. Unless the protective substances have free access to the area of infection the infective microbes have a highly beneficial nidus in which to multiply. Thus, the walls of a long-standing sinus may have a very poor blood-supply by reason of pent-up discharge, due to obstruction to outflow or coagulation. In such a case the sinus may be flushed out with a hypertonic salt and citrate solution consisting of 4 per cent. of sodium chloride and 1 per cent. of sodium citrate in sterilised water. The hypertonicity of the solution promotes increased osmosis through the walls of the sinus and a more copious flow of lymph results; moreover, the citrate prevents coagulation and the increased flow of lymph through the sinus walls finds its way to the surface uncoagulated. The contents of a cavity, such as the peritoneal fluid in tuberculous peritonitis, the exudate in tuberculous pleurisy, or the contents of an abscess may be low in protective substances while the circulating blood contains an excess. Drainage of such a cavity is followed by the introduction of fluids rich in protective substances derived from the blood and the cavity, formerly a suitable breeding place for the infecting microbe, now becomes a highly unsuitable breeding place by reason of the increase in protective substances.

To meet the conditions as to dosage indicated in the foregoing remarks we prepare at St. Mary's various concentrations of vaccine. The different concentrations are so arranged that by quite simple calculations doses from the lowest to the highest figure indicated above may be given. The following is a list of vaccines prepared and issued:—

Tubercle vaccine (T.R.).—Prepared from tubercle bacillary emulsion; in two strengths—viz., 1-2000th and 1-5000th milligramme of dried comminuted tubercle bacilli per cubic centimetre.

Staphylococcus vaccine.—Prepared from recently isolated virulent cultures of staphylococcus aureus and staphylococcus citreus; in three concentrations—viz., 100 millions, 200 millions, and 500 millions of cocci per cubic centimetre.

Streptococcus vaccine.—Prepared from recently isolated cultures of streptococcus obtained from cases of erysipelas; in three concentrations—viz., 5 millions, 10 millions, and 50 millions per cubic centimetre.

Gonococcus vaccine.—Prepared from cultures of proved immunising power; in two concentrations—viz., 5 millions and 10 millions of cocci per cubic centimetre.

Typhoid vaccine.—Prepared from a culture that has been frequently tested as to its immunising power; in two concentrations—viz., 1000 millions and 2000 millions of bacilli per cubic centimetre.

There is a probability that a vaccine of micrococcus neoformans will shortly be issued, as evidence is accruing of the beneficial results as regards lessening of pain and retardation of growth and secondary deposits in some kinds of cancer. It will probably be issued in one concentration—viz., 50 millions per cubic centimetre. 15 millions may be regarded as an appropriate initial dose and 25 millions as an average dose.

The T.R. is prepared from Koch's bacillary emulsion obtained from Meister Lucius and Brüning. It is to be noted that the dilutions are made and standardised on the *assumption that one cubic centimetre* of the product as issued by Meister Lucius and Brüning contains two, and not ten, milligrammes of dried comminuted tubercle bacilli. The stock staphylococcal vaccine, as issued to the profession, is used at St. Mary's for practically all staphylococcal lesions. Very rarely is it necessary to make a special autogenous vaccine. The stock streptococcal vaccine is used initially in acute cases. As soon as the infecting streptococcus is isolated a special vaccine is almost invariably prepared, these being far more specific. Rarely is it possible to prepare special gonococcal vaccines, so the stock vaccine has usually to be relied on.

Practically all other lesions, more especially those due to bacillus coli communis, are treated with specially prepared autogenous vaccines, and with regard to the latter there does not appear to be the slightest likelihood of a stock vaccine proving of any use in more than a small percentage of infections due to the colon bacillus.

VACCINES IN GENERAL PRACTICE.

BY LACHLAN GRANT, M.D., C.M. EDIN.;
T. H. CAMPBELL, M.B., CH.B. GLASG.;
AND
W. D. ANDERSON, M.A., M.B. CANTAB., M.R.C.S. ENG.

THE following cases having resisted the older forms of treatment it was decided to try the effect of vaccine therapy, and in these notes we will give a brief history of the cases, the *modus operandi* employed, and the results obtained.

CASE 1.—A man, aged 35 years, with a tuberculous history, consulted us in September, 1907, regarding a large swelling of two months' duration, on the left side of the neck, which extended from the angle of the jaw almost to the manubrium sterni. The case was one of advanced tuberculosis of the cervical glands which were evidently in a state of caseation and liquefaction. A few days later an incision was made into the dependent part of the swelling and the fluid contents were evacuated. The swelling subsided considerably and during the following three weeks the disease seemed to be held in abeyance. The improvement, however, was only temporary and the swelling advancing downwards another incision became necessary. In the course of another month, owing to the disease having spread over the manubrium, it was found expedient to make a third incision. The wounds were throughout treated antiseptically and all precautions were taken against the possible occurrence of mixed infection. Absolute rest in bed was enjoined, the patient's diet was regulated, and the best hygienic measures possible were adopted. This proved of little avail. *The wounds remained* open, sinuses discharging tuberculous débris. Indeed, an extension along the deep fascia into the mediastinum was feared. The affected part, after remaining unchanged for about three months, was subjected to the x rays. Irradiation was given on three separate occasions at intervals of one week, the dose on each occasion being 15 minutes of a soft tube with 0·35 milliampères passing and the anticathode 12 inches from the diseased tissue. After each irradiation a thin friable cicatrix formed over the wounds, but it invariably broke down again after a few days. The patient had been under our care for seven months and we now decided on a vaccine treatment.

On May 11th, 1908, an estimation of the patient's opsonic index for tubercle bacillus was made, and the index was found to be 0·7. On the same day 1-5000 cubic centimetre of T.R. was injected into the infrascapular region. This by protozoan parasites. It is already well established that trypanosomes become resistant to the drug employed and more difficult to drive out of the peripheral circulation with each fresh recurrence. Ehrlich also showed that in the case of rats treated with atoxyl the parasite itself, apart from the individual host, becomes resistant to the drug and when passed to fresh animals of the same species reaches finally a condition in which it is resistant or "fast" to the particular drug. The special point shown by the experiments described in the present communication is that this resistance only holds for the species of animals in which it has been established and disappears when the "fast" strain of trypanosomes is passed into another species of animal. 6. Observations on the Acidity and Alkalinity of the Blood in Trypanosome Infections, by M. Nierenstein, Ph.D., and J. W. Garrett. 7. A Contribution to the Morphology and Life History of Piroplasma Canis, by Anton Breinl and Edward Hindle. 8. The last paper in this number, by D'Emmerez De Charmoy, describes three new species of culex collected during the anti-malaria campaign in Mauritius in 1908.

The Edinburgh Medical Journal.—To the September number of this magazine Sir Alexander Russell Simpson contributes an illustrated paper on the use of Birth-stools in Egypt and incidentally relates the methods adopted among the lower classes in that country, which seem to have come down unchanged from early times. Dr. James H. Nicoll gives some statistics of hernia of the ovary in infants, and advocates operative treatment but not oöphorectomy; and Dr. H. A. Lediard records a case of successful treatment of a lymphangioma and comments on the unfavourable opinions expressed by the older generation of surgeons as to operative interference with these growths. Mr. Joseph Beard records the notes of two cases of meningitis admitted to hospital as enteric fever. Dr. J. Frank Crombie publishes the results obtained in some examinations of the blood in cases of whooping-cough, in which he found a leucocytosis to occur as a rule, the proportion of lymphocytes being always markedly increased; this feature may prove a useful aid in diagnosis. According to Dr. A. Dingwall-Fordyce Edinburgh milk contains on an average about 4 per cent. each of fat, sugar, and proteins—a simple and easily remembered formula.

ANNUAL REPORT FOR 1907 OF THE REGISTRAR-GENERAL FOR IRELAND.

WE are indebted to Sir Robert Matheson for a copy of this report which has just been issued by the Irish Stationery Office. This document derives additional value from the circumstance that it has been published within eight months of the close of the period to which it relates, in which regard it contrasts favourably with the corresponding reports for England and Scotland, the late appearance of which greatly impairs their usefulness for sanitary and statistical purposes. In some respects the Irish reports and returns differ from those of either of the sister divisions of the kingdom. In the first place, they contain particulars of mortality in the several social grades of the community, the importance of which will be apparent when we come to review the history of pulmonary tuberculosis in Ireland. In the next place, they contain, in addition to statistics of births, marriages, and deaths, all of which are presented on the English model, most valuable notes on the sanitary condition of the several registration districts, and inasmuch as these notes are contributed by registrars who are for the most part medical men, they possess on that account considerably increased value for preventive purposes.

The birth-rate of Ireland is stationary but still very low, amounting to no more than 23·2 per 1000 of the population. In the whole country the proportion of illegitimate to total births is 2·5 per cent., a proportion which compares favourably with that of both England and Scotland. Nevertheless the Irish provinces differ materially in this respect; for, whilst the illegitimate rate does not exceed 0·6 per cent. in Connaught, it is equal to 2·7 per cent. in Leinster and 3·3 per cent. in Ulster.

The Registrar-General reports a low rate of general mortality for the year 1907, namely 17·7 per 1000 living at all ages, which is slightly below the average for the preceding ten years. The rate was highest, 19·4 per 1000, in the province of Leinster, and lowest, 13·5 per 1000, in that of Connaught. The proportion ranged from 12·7 per 1000 in County Kerry, to 21·0 in Belfast, and 25·6 in Dublin. As a rough indication of the relation of poverty to mortality in Ireland it may be mentioned that there were registered in workhouses 10·4 per cent. of the total deaths in Connaught, 10·7 per cent. in Ulster, 16·8 per cent. in Leinster, and 19·6 per cent. in Munster.

From a well-arranged series of tables it appears that, as compared with the average in previous years, there has been in 1907 a reduction of mortality from each of the chief epidemic diseases, but that the mortality from influenza exceeds that of the previous year, and nearly equals the high average rate of the preceding decennium. It further appears that pneumonia has shown increased fatality in the year under notice, and that the deaths from tuberculosis have been equal in number to the average. Malignant disease is reported to have been more fatal than the average in 1907, but less fatal than in 1906. Taking the chief epidemic diseases separately, Sir Robert Matheson remarks on the significant reduction in the fatality of both scarlet fever and typhus fever. From the first-mentioned cause the mortality in 1907 was only one-sixth of what it had been ten years previously; and with regard to typhus fever we learn that whilst in the year 1880 there were 934 deaths from this disease the numbers had fallen to 391 in the year 1890 and to 128 in 1900, the deaths in 1907 having further fallen to 56. With the exception of the diarrhœal group the mortality from whooping-cough in 1907 exceeded that from any other epidemic disease, nevertheless the mortality in that year from whooping-cough was lower than the decennial average. Among other diseases of this group both diphtheria and enteric fever caused a lower fatality than the average in the year under notice, whilst diarrhœal diseases were considerably less destructive than usual.

An important and highly interesting section of the report is that which deals with the prevalence of cerebro-spinal fever in Ireland. Sir Robert Matheson tells us that the first recognised outbreak of this disease occurred in Dublin in the year 1846, on which occasion it lasted for four years. Again, in the period 1865–67 the disease appeared in that city, when it was known as "black death" or "malignant purpuric fever." In the year 1878, and again in 1900, the disease reappeared in Dublin, assuming epidemic form in the latter year. During the year 1907 631 deaths from cerebro-spinal fever were recorded in Ireland, of which not fewer than 495 occurred in the county borough of Belfast. From a table in the report it appears that in the large majority of the cases of this disease the fatal issue was exceedingly rapid, occurring generally within less than ten days from the commencement of illness. In Ireland, as in England, the use of the indefinite term cerebro-spinal meningitis to describe this disease has led to considerable uncertainty in the Register Office. The Registrar-General reports that in 327 cases in which cerebro-spinal meningitis appeared in the death certificates in the year under notice only 234 were finally classed, after inquiry, as cerebro-spinal fever, the greater part of the remainder having been classed as tuberculous meningitis or as other forms of tuberculosis. From these figures it is evident that a large portion of the medical practitioners in Ireland regard the terms "cerebro-spinal fever" and "cerebro-spinal meningitis" as synonymous. In the course of 1907 there were notified to the sanitary authority of Belfast 623 attacks of cerebro-spinal fever, of which 233 occurred in the March quarter, 291 in the June quarter, and 54 and 45 respectively in the September and December quarters of the year. The disease appears to have been particularly destructive to young children, not less than two-thirds of the total deaths having occurred within the first ten years of life. Whether or not exceptional measures of prevention were adopted in order to cope with the Belfast epidemic we are not informed in the report, but the disease seems to have rapidly diminished in fatality towards the end of the year.

The subject of tuberculosis, which Sir Robert Matheson

CASE 4.—A man, aged 70 years, complained in December, 1907, of cough and expectoration, loss of appetite, weakness, and shortness of breath, all of one month's duration. He volunteered the information that he sweated at night. There was a moderate nocturnal elevation of temperature. On percussion the note over the apex of the right lung was tympanitic. On auscultation there were clicking râles and amphoric breathing at the same spot. There was also a distinct history of tuberculous disease at this apex two years previously. At that time tubercle bacilli were found in the sputum. The treatment adopted was on the recognised hygienic, dietetic, and therapeutic lines, and under this *régime* the patient's condition slightly improved.

At the end of April, 1908, the sputum was examined and was found to be teeming with encapsulated pneumococci mixed with a considerable number of Friedländer's pneumo-bacilli, but repeated examination by the more elaborate methods failed to detect any bacillus of tubercle. It was therefore concluded that the focus of tubercle was locked up and that we had to deal with an invasion of the right apex by pneumococci, and it seemed a rational treatment to attack these organisms with a suitable vaccine. This was therefore prepared from the patient's own strain of pneumococci. We considered that the clearing up of the pneumococcic infection would probably be a good step towards the resolution of any tuberculous process that might be going forward.

On May 29th the patient received the first dose of vaccine. This dose contained 15,000,000 of mixed pneumococci and pneumo-bacilli, the former being largely in excess of the latter. Next day there was a very slight reaction which was followed by no discernible improvement in the patient's condition.

On June 6th 15,000,000 were again injected, the patient's opsonic index being then 1·6 for pneumococci. There was a slight reaction, a feeling of malaise and increased cough and expectoration, followed in the course of the day by a sense of well-being. The temperature now remained normal and the night-sweats were less troublesome. On the 10th he was allowed out of bed for an hour. On the 17th 30,000,000 were injected. After the reaction had passed off there was further improvement. Cough and expectoration were diminished, the patient felt stronger, and was able to sit up for four hours. The appetite was much better. An examination of the sputum showed a remarkable diminution in the pneumococci and no tubercle bacilli were to be found. An opsonic estimation made on this day showed an index of 1·0 for pneumococci and 1·3 for pneumo-bacilli. On the 30th he was allowed out on warm days.

On July 2nd another injection of 30,000,000 was given. A few days after this the patient was able to go for an hour's walk. The improvement was progressive and on the 27th he was able to do a little manual work. All the signs of a cavity were, however, still present at the right apex. On the 28th 10,000,000 were injected, and after the reaction had passed off the patient's condition continued to improve. He was soon well enough to work. Since early in August he has been engaged in a regular, though light, occupation, and says that he feels better than he has done for nearly a year. There are still cough and expectoration, but the cough is slight and the expectoration very scanty. A few râles are to be heard at the right apex, but on the whole the improvement is very great indeed.

Conclusions.—The results in the foregoing cases have so far been most satisfactory and we venture to attribute this to the action of the vaccines. In those cases treated with tuberculin the following points are of note:—

1. The scars resulting were soft, pliable, and the disfigurement slight.

2. Recovery under the treatment seemed rapid, and this implied saving of suffering and expense to the patient and anxiety to the medical attendants.

3. The absence of severe surgical measures minimised the risk of a general tuberculous infection and obviated that slight risk which always attends general anæsthesia.

4. Although opsonic estimations were only made occasionally during the treatment, they suggested that the index was being steadily raised, and from this it is probable that for some time, at least, the patients will be less susceptible to attacks by the same bacterium. Surgical measures alone may achieve this indirectly, inasmuch as they rid the body of the focus of disease, but it is questionable if they are capable of raising the standard of defence to the same high level as that induced by vaccine therapy.

It may perhaps be right to conclude by saying that much expense and valuable time were saved to the patients and to ourselves by the fact that the microscopical work, the electrical treatment, the preparation of vaccines, and the opsonic estimations were all conducted in our own laboratories.

Ballachulish, Argyllshire.

THE SANITATION OF MINES.[1]

BY FRANK SHUFFLEBOTHAM, M.A., M.B., B.C. CANTAB.

THE question of the sanitation of mines has been brought prominently to our notice of late years through the outbreak of ankylostomiasis in Westphalia, Belgium, and other European countries, as well as among the tin miners of Cornwall. In each district the disease has affected large numbers of workers, in some cases to such an extent as to be a great menace to the industry. The absence of sanitary arrangements underground has been the principal cause of so many men being struck down by this disease, and it has been due mainly to the institution of elaborate sanitary arrangements that the disease has been eradicated, and even then in each epidemic it has been a matter of many months, and in some districts of several years, before the disease disappeared.

Proper sanitary arrangements are desirable in mines on general hygienic grounds, but they are necessary on account of the dangers which may arise through their absence. In the first place I wish to show how ankylostomiasis can be spread among miners through the want of proper sanitation underground, and I will describe briefly the nature of the disease, so that this will be all the more easily understood.

Nature of Ankylostomiasis.

Ankylostomiasis is a disease caused by the presence of a small worm known as the ankylostoma duodenale in the upper part of the small intestine. The worm attaches itself to the mucous membrane of the bowel by means of hooks which are situated round its mouth. It does not reproduce itself within the intestine but the female lays an enormous number of microscopically small oval eggs which pass away in the fæces. The eggs hatch out into larvæ under favourable conditions of temperature and moisture and in the presence of oxygen and absence of daylight. The eggs will not hatch out in the intestine owing to the lack of free oxygen. The larvæ continue to grow and after a short time they develop a capsule. It is in this state that they enter the human body. Miners often relieve themselves underground and if they are infected with ankylostoma then the motions would be a source of danger. The hands of their fellow-workers might become contaminated with infected fæcal matter and when they take their food at "snapping-time" they would swallow some of the encapsuled larvæ which in the intestine develop into full-grown worms. The worm may live in the human intestine for several years. The disease is endemic in many tropical and subtropical countries but when found in temperate climates it is practically confined to miners and workers in tunnels.

Symptoms and diagnosis of the disease.—The symptoms are: (1) anæmia with its usual accompaniments, pallor, shortness of breath on exertion, palpitation, giddiness, and fainting; (2) gastro-intestinal disturbances; and (3) in the outbreak in Cornwall skin symptoms were found. The positive diagnosis can only be made when the eggs are found in the stools. For the methods of detecting the eggs I would refer to the Home Office Memorandum of Feb. 16th, 1904, and to papers by Dr. A. E. Boycott and Dr. J. S. Haldane in the *Journal of Hygiene*, January, 1903, and January, 1904.

It must be remembered that only a certain percentage of those infected with ankylostoma show symptoms of the disease. This is of great importance from the fact that they are just as great a menace as those whose symptoms are marked. The examination of the blood, however, will show

THE LANCET.

LONDON: SATURDAY, SEPTEMBER 26, 1908.

The Present Condition of Pharmacy.

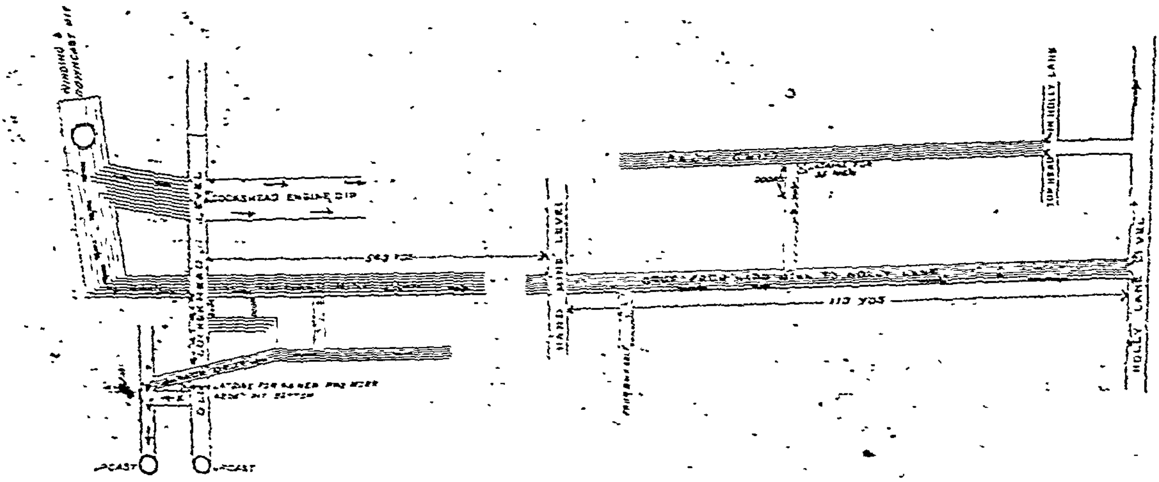
PHARMACY still forms one of the subjects of the ordinary medical curriculum and it is obvious that a knowledge of the various mineral and vegetable preparations which are used as drugs is essential for every practitioner of medicine. At the present time, however, the same intimate knowledge of pharmacy is not required as was the case in past generations of medical men. The evolution of the pharmacist has gradually introduced a new element into medical practice, many practitioners confining themselves to writing prescriptions and leaving the actual compounding of the ingredients to the pharmacist or, to use a more familiar term, the druggist. At the meeting of the British Pharmaceutical Conference recently held in Aberdeen the President, Mr. ROBERT WRIGHT, delivered an interesting address on "Pharmacy—its Rise, Province, and Present Condition," in which he considered in detail many points which are constantly arising in connexion with the preparation and the compounding of drugs, dealing, however, with the ethical side and not with the scientific.

Having sketched in brief outline the rise of pharmacy, Mr. WRIGHT proceeded to make a few remarks upon its province. He correctly maintained that pharmacy included within its range the provision and supplying to the public of everything capable of employment for the relief or cure of any ailment or disease to which human beings are subject. As regards drugs, this includes their collection and the investigation of their botanical character, their chemical and physical properties, and their composition; also their elaboration and exhibition in the form of galenical preparations of approved type, and their distribution to the public, either directly or indirectly. This consideration at once raises the much disputed question of the relationship which should exist between the medical practitioner and the druggist. Mr. WRIGHT stated the ideal condition in a few words: "The proper sphere of medicine lies in the diagnosis of disease and its treatment, including the prescribing of remedies; that of pharmacy in the compounding of drugs and the dispensing of medicines." Could this principle be always and everywhere carried out in practice no difficulties would arise; but Mr. WRIGHT recognises the complexity of the situation and in his address gave his opinion freely on the subject. With most of his remarks we are in accord. He stated the case for the pharmacist with fairness and exactness and uttered a note of warning to those of his colleagues who from "mercenary motives ...... should be tempted to transgress the laws of prudence and common sense, and to administer remedies in cases with which only the trained practitioner should deal." He then went on to remark: "We claim that the counter-prescribing of simple remedies for simple ailments is quite in harmony with the general fitness of things, and an educated and conscientious pharmacist, knowing by experience the difficulties often met with in diagnosing even 'simple' ailments, will in any case of doubt at once draw the line and refuse to prescribe." The important point in this dictum is that every pharmacist should clearly know where to "draw the line," and there is every temptation to extend the limit of counter-prescribing rather than to lessen it. To take an example. It is a daily event for a customer to enter a druggist's shop and to ask for a remedy against constipation. A pill or draught is given but unless some discrimination is used, serious results may follow. It would be impossible for the druggist to diagnose between simple constipation, intestinal obstruction in any form, or ambulatory enteric fever, and the careless use of purgatives might thus prove a great danger. We agree with Mr. WRIGHT that there is another side to the question—namely, the dispensing of drugs by medical practitioners. But we venture to suggest that he puts the case too strongly when he speaks about "the doctor who for complaints which he is supposed to be able to diagnose correctly administers drugs of the proper methods of exhibiting which he is totally, or almost totally, ignorant." We regret that he should have made such a condemnation in an address which was otherwise so moderately expressed. The medical student is now compelled to attend lectures on materia medica and to go through a course of instruction in pharmacy which gives him a fair knowledge of the subject. This is essential, for although, as has been ably argued in our columns,[1] it would be advantageous to the medical profession if medical men prescribed their medicine, leaving the making up of the formulæ to the dispensing chemist, yet such a course is not practicable. There are many neighbourhoods which are too poor and too sparsely populated to support a dispensing chemist and hence the practitioners residing in that district are obliged to dispense their own drugs.

Mr. WRIGHT expressed himself in no doubtful terms in regard to the sale of patent or quack medicines. He quoted figures which amply proved that notwithstanding the wide diffusion of knowledge, the spread of education, and the raising of the standard of intelligence among the people, the appeal of the quack and the charlatan to the credulity of the public meets with a readier response than ever. We have again and again protested against the exploiting of such preparations by the lay press but with very little success. Mr. WRIGHT was pessimistic in regard to the part which the pharmacist could play in helping to mitigate the evil, for he remarked: "What the public demands in the shape of medicine we ought, I think, unquestionably to supply." We doubt the propriety of this remark; nevertheless, he is probably correct in thinking that the dispensing chemist can do but little and that the real and only effective remedy lies with the legislature, and he indicated the direction which he considered such legislation should take. He suggested that the cost of the patent burnt. (It is far better to take the pans to the surface to be emptied rather than to empty them in the far parts of the mine.) Mr. Salt tells me that the closets are largely used not only by the men working at the pit bottom and along the roadways but also by miners working at distant parts of the mine who use them either before commencing work or when they are waiting at the pit bottom to return to the surface. Previous to the erection of these closets the men had to relieve themselves in cross-cuts and disused roadways, with the result that the ground in these places was contaminated with fæcal matter. Under the present conditions the men use the conveniences provided for them and from the conversations I had with them they very much appreciate this accommodation. The plan shows the position of these closets and the distribution of the men in the mine at those points. On the surface there are two closets and three urinals provided.

---

[1] THE LANCET, April 1st, 1905, p. 878.



Plan of sanitary arrangements at Norton Colliery, Stoke-on-Trent.

Sanitary arrangements are not necessary for men employed at the working face because the face is continually moving and the men can retire into the goaf where *no one* can come in contact with the motions. The ventilating air is not contaminated under these conditions. An exception, however, must be made to this general statement. Where the dips are so steep that the men are obliged to reach the working face by ladders, *portable pails* should be provided because the goaf is always above the men, and if the men relieved themselves in the roadway at the top of the dip they would get their hands contaminated with fæcal matter in ascending and descending the ladders.

The evidence already given before the Royal Commission on Mines shows that in some districts there is an entire absence of sanitary arrangements underground. At some isolated collieries in Yorkshire, Lancashire, and North Staffordshire sanitary arrangements have been instituted, but in other districts no provision is apparently made in this direction. I do not believe that in either Scotland or Wales, where there are large mining communities, there is a single colliery possessing any sanitary conveniences underground.

It is said by some that were closets universally provided in mines the men would not avail themselves of these arrangements, but I do not think this is true. As far as my experience goes in North Staffordshire the men appreciate these sanitary improvements. I have never heard of a single case of a miner refusing to take advantage of them. As long as the closets are well looked after and the seats kept clean so long will the men use them. I have spoken to miners working in mines where no sanitary arrangements are made and they would gladly welcome the introduction of closets.

I believe it should be made compulsory for all mine-owners to make suitable sanitary provisions at each colliery, both underground and on the surface, on the lines which I have described exist at the Norton Colliery. The best way this could be brought about would be by the extension of the Special Rules made by the Secretary of State and applied to mines in Cornwall during the outbreak of ankylostomiasis in that district to the whole of the mines in the country. These rules require that:

> The owner, agent or manager shall cause a sufficient number of suitable sanitary conveniences to be provided above and below ground in suitable and convenient places for the use of the persons employed, and to be constantly kept in a cleanly and sanitary condition, and no person shall relieve his bowels below ground elsewhere than in those conveniences. [An exception would have to be recognised to this section of the rules in the case of those miners who work "at the face," and who are able to retire into the goaf.] No person shall soil or render unfit for use in any way any convenience or sanitary utensil or appliance provided for the use of the persons employed. Pump cisterns, sumps and water accumulations in the mines shall not be directly or indirectly used as sanitary conveniences. It shall be the duty of the owner, agent or manager to see that all plant, material and other things necessary to enable the above rules to be carried out are provided and maintained in working order, and to appoint sufficient competent officials to enforce the requirements of the rules, and for this purpose to assign to each his respective duties. It shall be the duty of the officials so appointed to see that the rules are observed by all persons employed in the mine and to carry out the duties assigned to them. It shall be the duty of all persons employed in the mine to comply with the requirements of the rules and with such instructions as may be given to them by the officials with a view to such requirements being carried out.

In conclusion, I consider that this subject is of sufficient importance to receive the attention of mine-owners, and that it should be dealt with by professors of mining in the universities, by county council lecturers in their classes, and that the men's leaders should not neglect to instruct the working miners to coöperate with their employers so as to make the sanitary conditions of mines more satisfactory in the future.

Newcastle-under-Lyme.

THE FORMIC ACID DERIVATIVES IN THE TREATMENT OF CANCER.

By J. HOWELL EVANS, M.A., M.B., M.CH. OXON., F.R.C.S. ENG.,

HUNTERIAN PROFESSOR, ROYAL COLLEGE OF SURGEONS OF ENGLAND, 1907; ASSISTANT SURGEON TO THE PRINCE OF WALES'S GENERAL HOSPITAL, N.; ASSISTANT SURGEON TO THE CANCER HOSPITAL, S.W.

I WISH to record for the readers of THE LANCET the details of some work systematically carried out since October, 1906, in connexion with formic acid and its derivatives. As topical applications or internal medications I have employed the following preparations: 1. Formalin; formamint lozenges. 2. Formic acid; formates: glyceroformates. 3. Infusio A.F. (formula of the Cancer Hospital Pharmacopœia): an infusion of the common nettle either grown under glass or plucked from its beds, according to the season of the year, so that the fresh herb has been regularly used. 4. Nettle fomentations. 5. Douches, irrigations, and rectal injections of formaldehyde and nettle preparations. We may here briefly consider some of the derivatives of the lowest member of the paraffin or methane series.

Methaldehyde, synonymous with formaldehyde (formalin is a 40 per cent. solution of *formaldehyde*), has long been

Europe. The great protective barrier formed by the 800 miles of barren desert between Medina and Damascus has now been annihilated, and a four days' journey by train has been substituted for a six weeks' march on camel-back or on foot. The greatly increased danger of the carriage of cholera or other disease by returning pilgrims is too obvious to need dwelling on at length. And at the present moment the danger is no imaginary one. Cholera is spreading rapidly and widely in Russia, as our columns have recently shown, and it is scarcely to be hoped that the coming Haj will escape infection. The measures to be applied this year on the Hedjaz railway are, we gather, to be of an improvised character, though they will show a great advance on those applied last year. We are only expressing an opinion very widely held in saying that it is of real necessity that the permanent sanitary defence of the line should be provided for without too long a delay, and that the measures of defence should be adequate to meet the risk and should be applied on a scale proportioned to the number of pilgrims who may be expected to use this new and convenient mode of returning from the Holy Cities of Islam.

The Nature of Menstruation.

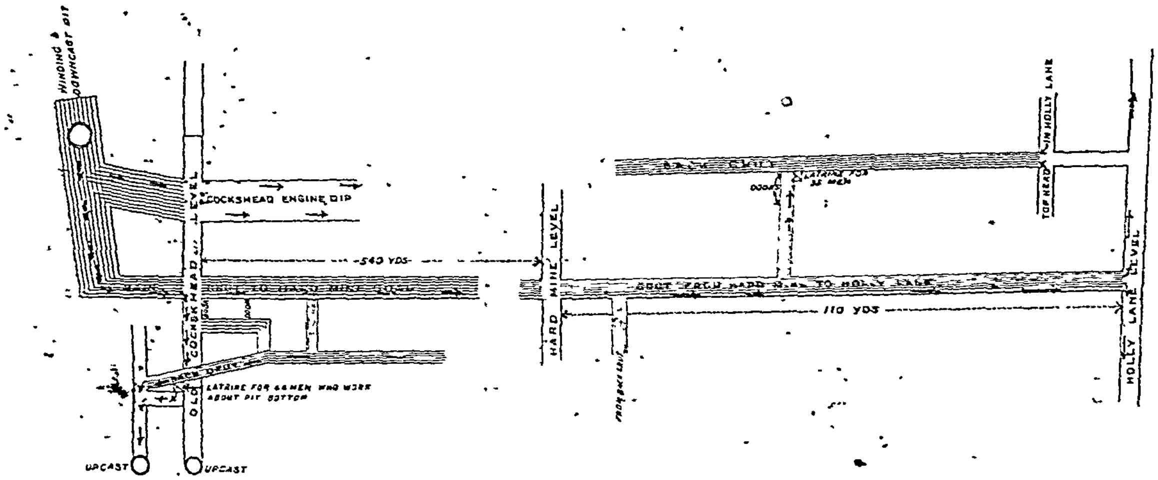
IN all ages—ancient, mediæval, and modern—the process of menstruation has been regarded with much interest by students of nature, whether physicians or philosophers. Among the early Greek writers it was thought that the menses represented the seed of the woman and that the union of the female seed with that of the male was necessary for conception to occur. The saying usually attributed to ARISTOTLE, "The blood of the menses is the marble, the semen is the sculptor, and the fœtus is the statue," well expresses the views as to the importance of these two substances held by the thinkers of his day. It is not surprising, when such ideas as to the meaning of generation were current, that various explanations as to the origin of monsters should have been based upon the possibility of their being due to some alteration in the character or condition of one or other of the two seeds. From this it was but a short step to the conception that intercourse with a menstruating woman was likely to give rise to various forms of monsters, and such an idea was no doubt fostered by the various rules and prohibitives laid down in the Old Testament regarding coitus during, or immediately after the cessation of, the menses. As BALLANTYNE points out, in the non-canonical book of Esdras the following passage occurs: "Menstruous women shall bring forth monsters"; and according to the Talmud the infant conceived during the period of impurity was regarded as certain to be an epileptic, a drunkard, a cretin, or insane. AMBROSE PARÉ, too, considered intercourse between parents at such times as they ought to abstain by the command of GOD and the Church to be one of the causes of monsters. Not only did the old writers think that the menses played the chief part in the production of monstrous births but they also taught that the menstruating woman was unclean and to be shunned; thus PLINY tells us: "On the approach of a woman in this state, must will become sour, seeds which are touched by her will become sterile, grass wither away, garden plants are parched up, and the fruit will fall from the tree beneath which she sits." He also says that menstruating women in Cappadocia were made to perambulate the fields to preserve the vegetation from worms and caterpillars.

Such curious notions as these with regard to the nature of the menses prevailed until the latter part of the seventeenth century, when the researches of HARVEY, DE GRAAF, and LUDWIG HAMM of Dantzig, who first discovered living spermatozoa, threw a new light on the real nature of generation and the structures concerned therein. It was still, however, thought that the discharge of the menses formed a monthly cleansing process and many customs founded upon this view, such as the isolation of menstruating women, can be traced among the inhabitants of all parts of the world, even up to quite recent times. Since the discovery of the process of ovulation the theory that there must be some relation between the discharge of an ovum from the ovary and the occurrence of menstruation has always been held; and one of the most interesting problems connected with pregnancy is the relation of these two processes to one another, whether we consider merely the time of their occurrence or their possible causal relationship. The researches of LEOPOLD and others have proved beyond doubt that ovulation can occur without menstruation and menstruation without ovulation; at the same time there is an increasing tendency amongst most of the writers who have made a special study of this subject to believe that there is some relationship between them—that the occurrence of ovulation favours the onset of menstruation or *vice versâ*. The fact that pregnancy puts a stop to the appearance of the menses leads naturally to the hypothesis that if impregnation fails to occur the ovum is cast off with the mucous membrane of the uterus and that menstruation is therefore an abortion of an unfertilised ovum. Of late years most authorities are inclined to accept the views so ably put forward by HEAPE, and to regard the menstrual cycle in man and monkeys as homologous with the œstrus cycle of the lower mammals, menstruation being represented by the pro-œstrus, while the period of œstrus or rut is thought to correspond in the human female to the days immediately following the cessation of menstruation, when as a rule sexual desire is at a maximum. It may well be that at the present time menstruation should be regarded as equivalent to the pro-œstrus stage in animals, but since there are many women in whom the sexual feelings are most highly developed during and not after menstruation, is it not possible that in the course of many generations the teaching that intercourse at this period was harmful and the fact that it was interdicted by the Church may have led to an involuntary suppression of her natural feelings on the part of the modest woman, and so to the gradual development of the idea that menstruation and rut are not in reality the same thing?

In their recent work on an early human ovum[1] TEACHER and BRYCE have propounded a new and most interesting burnt. (It is far better to take the pans to the surface to be emptied rather than to empty them in the far parts of the mine.) Mr. Salt tells me that the closets are largely used not only by the men working at the pit bottom and along the roadways but also by miners working at distant parts of the mine who use them either before commencing work or when they are waiting at the pit bottom to return to the surface. Previous to the erection of these closets the men had to relieve themselves in cross-cuts and disused roadways, with the result that the ground in these places was contaminated with fæcal matter. Under the present conditions the men use the conveniences provided for them and from the conversations I had with them they very much appreciate this accommodation. The plan shows the position of these closets and the distribution of the men in the mine at those points. On the surface there are two closets and three urinals provided.

---

[1] See p. 941 of the present issue of THE LANCET.



Plan of sanitary arrangements at Norton Colliery, Stoke-on-Trent.

Sanitary arrangements are not necessary for men employed at the working face because the face is continually moving and the men can retire into the goaf where no one can come in contact with the motions. The ventilating air is not contaminated under these conditions. An exception, however, must be made to this general statement. Where the dips are so steep that the men are obliged to reach the working face by ladders, *portable pails* should be provided because the goaf is always above the men, and if the men relieved themselves in the roadway at the top of the dip they would get their hands contaminated with fæcal matter in ascending and descending the ladders.

The evidence already given before the Royal Commission on Mines shows that in some districts there is an entire absence of sanitary arrangements underground. At some isolated collieries in Yorkshire, Lancashire, and North Staffordshire sanitary arrangements have been instituted, but in other districts no provision is apparently made in this direction. I do not believe that in either Scotland or Wales, where there are large mining communities, there is a single colliery possessing any sanitary conveniences underground.

It is said by some that were closets universally provided in mines the men would not avail themselves of these arrangements, but I do not think this is true. As far as my experience goes in North Staffordshire the men appreciate these sanitary improvements. I have never heard of a single case of a miner refusing to take advantage of them. As long as the closets are well looked after and the seats kept clean so long will the men use them. I have spoken to miners working in mines where no sanitary arrangements are made and they would gladly welcome the introduction of closets.

I believe it should be made compulsory for all mine-owners to make suitable sanitary provisions at each colliery, both underground and on the surface, on the lines which I have described exist at the Norton Colliery. The best way this could be brought about would be by the extension of the Special Rules made by the Secretary of State and applied to mines in Cornwall during the outbreak of ankylostomiasis in that district to the whole of the mines in the country. These rules require that:

> The owner, agent or manager shall cause a sufficient number of suitable sanitary conveniences to be provided above and below ground in suitable and convenient places for the use of the persons employed, and to be constantly kept in a cleanly and sanitary condition, and no person shall relieve his bowels below ground elsewhere than in those conveniences. [An exception would have to be recognised to this section of the rules in the case of those miners who work "at the face," and who are able to retire into the goaf.] No person shall soil or render unfit for use in any way any convenience or sanitary utensil or appliance provided for the use of the persons employed. Pump cisterns, sumps and water accumulations in the mines shall not be directly or indirectly used as sanitary conveniences. It shall be the duty of the owner, agent or manager to see that all plant, material and other things necessary to enable the above rules to be carried out are provided and maintained in working order, and to appoint sufficient competent officials to enforce the requirements of the rules, and for this purpose to assign to each his respective duties. It shall be the duty of the officials so appointed to see that the rules are observed by all persons employed in the mine and to carry out the duties assigned to them. It shall be the duty of all persons employed in the mine to comply with the requirements of the rules and with such instructions as may be given to them by the officials with a view to such requirements being carried out.

In conclusion, I consider that this subject is of sufficient importance to receive the attention of mine-owners, and that it should be dealt with by professors of mining in the universities, by county council lecturers in their classes, and that the men's leaders should not neglect to instruct the working miners to coöperate with their employers so as to make the sanitary conditions of mines more satisfactory in the future.

Newcastle-under-Lyme.

THE FORMIC ACID DERIVATIVES IN THE TREATMENT OF CANCER.

BY J. HOWELL EVANS, M.A., M.B., M.CH. OXON., F.R.C.S. ENG.,

HUNTERIAN PROFESSOR, ROYAL COLLEGE OF SURGEONS OF ENGLAND, 1907; ASSISTANT SURGEON TO THE PRINCE OF WALES'S GENERAL HOSPITAL, N.; ASSISTANT SURGEON TO THE CANCER HOSPITAL, S.W.

I WISH to record for the readers of THE LANCET the details of some work systematically carried out since October, 1906, in connexion with formic acid and its derivatives. As topical applications or internal medications I have employed the following preparations: 1. Formalin; formamint lozenges. 2. *Formic acid*; *formates*; glyceroformates. 3. Infusio A.F. (formula of the Cancer Hospital Pharmacopœia): an infusion of the common nettle either grown under glass or plucked from its beds, according to the season of the year, so that the fresh herb has been regularly used. 4. Nettle fomentations. 5. Douches, irrigations, and rectal injections of formaldehyde and nettle preparations. We may here briefly consider some of the derivatives of the lowest member of the paraffin or methane series.

Methaldehyde, synonymous with formaldehyde (formalin is a 40 per cent. solution of formaldehyde), has long been

Europe. The great protective barrier formed by the 800 miles of barren desert between Medina and Damascus has now been annihilated, and a four days' journey by train has been substituted for a six weeks' march on camel-back or on foot. The greatly increased danger of the carriage of cholera or other disease by returning pilgrims is too obvious to need dwelling on at length. And at the present moment the danger is no imaginary one. Cholera is spreading rapidly and widely in Russia, as our columns have recently shown, and it is scarcely to be hoped that the coming Haj will escape infection. The measures to be applied this year on the Hedjaz railway are, we gather, to be of an improvised character, though they will show a great advance on those applied last year. We are only expressing an opinion very widely held in saying that it is of real necessity that the permanent sanitary defence of the line should be provided for without too long a delay, and that the measures of defence should be adequate to meet the risk and should be applied on a scale proportioned to the number of pilgrims who may be expected to use this new and convenient mode of returning from the Holy Cities of Islam.

The Nature of Menstruation.

IN all ages—ancient, mediæval, and modern—the process of menstruation has been regarded with much interest by students of nature, whether physicians or philosophers. Among the early Greek writers it was thought that the menses represented the seed of the woman and that the union of the female seed with that of the male was necessary for conception to occur. The saying usually attributed to ARISTOTLE, "The blood of the menses is the marble, the semen is the sculptor, and the fœtus is the statue," well expresses the views as to the importance of these two substances held by the thinkers of his day. It is not surprising, when such ideas as to the meaning of generation were current, that various explanations as to the origin of monsters should have been based upon the possibility of their being due to some alteration in the character or condition of one or other of the two seeds. From this it was but a short step to the conception that intercourse with a menstruating woman was likely to give rise to various forms of monsters, and such an idea was no doubt fostered by the various rules and prohibitives laid down in the Old Testament regarding coitus during, or immediately after the cessation of, the menses. As BALLANTYNE points out, in the non-canonical book of Esdras the following passage occurs: "Menstruous women shall bring forth monsters"; and according to the Talmud the infant conceived during the period of impurity was regarded as certain to be an epileptic, a drunkard, a cretin, or insane. AMBROSE PARÉ, too, considered intercourse between parents at such times as they ought to abstain by the command of GOD and the Church to be one of the causes of monsters. Not only did the old writers think that the menses played the chief part in the production of monstrous births but they also taught that the menstruating woman was unclean and to be shunned; thus PLINY tells us: "On the approach of a woman in this state, must will become sour, seeds which are touched by her will become sterile, grass wither away, garden plants are parched up, and the fruit will fall from the tree beneath which she sits." He also says that menstruating women in Cappadocia were made to perambulate the fields to preserve the vegetation from worms and caterpillars.

Such curious notions as these with regard to the nature of the menses prevailed until the latter part of the seventeenth century, when the researches of HARVEY, DE GRAAF, and LUDWIG HAMM of Dantzig, who first discovered living spermatozoa, threw a new light on the real nature of generation and the structures concerned therein. It was still, however, thought that the discharge of the menses formed a monthly cleansing process and many customs founded upon this view, such as the isolation of menstruating women, can be traced among the inhabitants of all parts of the world, even up to quite recent times. Since the discovery of the process of ovulation the theory that there must be some relation between the discharge of an ovum from the ovary and the occurrence of menstruation has always been held; and one of the most interesting problems connected with pregnancy is the relation of these two processes to one another, whether we consider merely the time of their occurrence or their possible causal relationship. The researches of LEOPOLD and others have proved beyond doubt that ovulation can occur without menstruation and menstruation without ovulation; at the same time there is an increasing tendency amongst most of the writers who have made a special study of this subject to believe that there is some relationship between them—that the occurrence of ovulation favours the onset of menstruation or *vice versâ*. The fact that pregnancy puts a stop to the appearance of the menses leads naturally to the hypothesis that if impregnation fails to occur the ovum is cast off with the mucous membrane of the uterus and that menstruation is therefore an abortion of an unfertilised ovum. Of late years most authorities are inclined to accept the views so ably put forward by HEAPE, and to regard the menstrual cycle in man and monkeys as homologous with the œstrus cycle of the lower mammals, menstruation being represented by the pro-œstrus, while the period of œstrus or rut is thought to correspond in the human female to the days immediately following the cessation of menstruation, when as a rule sexual desire is at a maximum. It may well be that at the present time menstruation should be regarded as equivalent to the pro-œstrus stage in animals, but since there are many women in whom the sexual feelings are most highly developed during and not after menstruation, is it not possible that in the course of many generations the teaching that intercourse at this period was harmful and the fact that it was interdicted by the Church may have led to an involuntary suppression of her natural feelings on the part of the modest woman, and so to the gradual development of the idea that menstruation and rut are not in reality the same thing?

In their recent work on an early human ovum[1] TEACHER and BRYCE have propounded a new and most interesting clot and shreds of placenta were removed from the lower half of the uterus—the soft mass at the top not being dislodged. The curette was only in use a minute when it was noticed that a yellow fat-like substance came away in one scraping. As the flushing curette was not in working order my assistant passed me the ovum forceps to deal with what we considered the placenta attached to the fundus. It was gently withdrawn and to our extreme surprise was seen to be a coil of the large intestine! It was immediately replaced, and a long saline injection was given through the wound into the abdomen. The patient's pulse had become running and feeble; she was given strychnine and ergotinin hypodermically and the saline injection was continued until she recovered. A strip of gauze was put into the uterus, which was beginning to contract, and the vagina was lightly packed. The patient's condition was not at the moment such as to allow of an immediate laparotomy, so she was taken to the ward and there watched, being given hypodermic injections of strychnine and ergotinin. She was placed with her head lower than her feet for the first hour.

---

[1] See p. 941 of the present issue of THE LANCET.

Dr. Agnes C. Scott, of St. Stephen's Hospital, was called in in consultation. The patient's pulse had improved and was full and strong. She was not vomiting unduly and seemed fairly comfortable, so it was decided to push the ergotinin and to place her in Fowler's position; this was done. She gradually improved and was kept on albumin water and white wine whey at first and then began taking milk. Her pain had disappeared and when she had been six days in hospital she felt well enough to want to go home. Meanwhile she was kept in Fowler's position except for a short time on the fifth and sixth days, when her bed was lowered and she was allowed to be raised on pillows. She was having no discharge and no pain; her temperature was normal and the pulse was good. On the night of the seventh day the night nurse noticed a discharge on the diaper. It was slightly yellow and had a faint odour of digestive fluid. Some pain was felt by the patient in the right iliac region; she was otherwise doing well. A laparotomy was decided on as the discharge continued and made us suspect a rent in the intestine. The patient's pulse on the eighth evening was not very satisfactory. On opening the abdomen it was found that the omentum was closely adherent all round the lower part, which was completely shut off. It was attached to the brim of the pelvis and, indeed, was so firmly held down that it was decided not to risk opening it. The abdomen was closed and the patient was put to bed. Her condition did not justify the extensive radical and plastic measures that were necessary. Her condition suddenly got worse two days after. The tenderness of which she had complained (before admission) in the right iliac region increased. She was unable to retain anything but albumin water; her pulse got very bad. On the twelfth day after admission she died.

It was discovered later that at her confinement she had an untrained Indian midwife who is one of a class that generally pull on the child and sometimes, to assist labour, *stand* on the fundus. The patient had been unable to recover her strength after the confinement and had had five attacks of extreme colic in four weeks. The pain was most severe in the right iliac fossa. She was doubled up with it and had vomiting and constipation. The pain lasted for from four to six days each time, being acute for about 36 hours.

No post-mortem examination was allowed but from what was seen and felt at the operation the case was one in which there had been a long transverse tear in the fundus (about two inches long at the date of operation). Lying on this tear and protruding into the uterus was a coil of intestine which the subsequent examination proved to have been shut off by the adherent peritoneum. The dislodging of this coil and the contractions of the uterus in which it was, perhaps, again caught may have produced the later symptoms which preceded death.

Delhi.

UNIVERSITY OF OXFORD.—Mr. H. C. Bazett, B.A., Wadham College, was the successful candidate in the recent examination for the Universities' scholarship at St. Thomas's Hospital. Mr. Bazett took a first class in physiology in the final schools last July.

DIFFUSE PAINFUL LIPOMA OF THE FOOT.

BY A. H. TUBBY, M.S. LOND.,

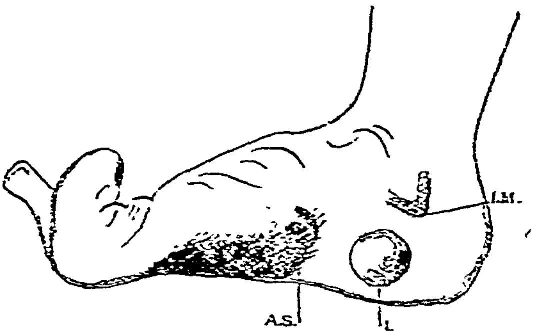
SURGEON TO WESTMINSTER HOSPITAL AND IN CHARGE OF THE ORTHOPÆDIC DEPARTMENT, ETC.

DURING the past ten years some examples of an affection which I believe to be hitherto undescribed have come under my notice. The trouble, although a slight one, yet causes considerable difficulty and pain in walking and from its position mistakes easily arise in diagnosis. I append notes of two cases.

CASE 1.—A hospital nurse, aged 25 years, was admitted to Westminster Hospital on May 24th, 1906. She had been nursing for nine months. Three months previously she first experienced aching pains in the soles and inside of the feet. The pain was worse on rising in the morning and for about an hour afterwards, but it continued to trouble her for the whole day. Almost instantaneous relief was obtained on lying down or resting the foot, but the pain came on again on walking. On examination, on looking at the feet on the inner side and just below the sustentacula tali, an oval swelling was visible on each foot. The growths encroached on the weight-bearing surface of the feet; in size they measured 1 inch by 1½ inches. Their characters were those of indolent growths, moderately well defined and without signs of inflammation over them. They were painful to the touch and particularly so to deep pressure. The feet were not flat in the ordinary sense of the word. The swellings were diagnosed as diffuse lipoma from an experience of similar cases. An operation was undertaken and when the swellings were incised they were found to be of a fatty nature. They were not encapsuled; but the globules of fat of which they were composed were considerably larger and lighter in colour than the surrounding normal fat, so that there was no difficulty in dissecting away the whole of the growths. It was noticeable that the tumours were highly vascular and bled considerably. The wounds were closed in the ordinary way and healed without difficulty.

Dr. R. G. Hebb, the physician-pathologist to the hospital, made a microscopical examination, and reported that no evidences of nerve endings or of nævoid tissue were found in the tissue, which consisted entirely of fat. The patient presented herself for examination at intervals but the growths did not recur.

CASE 2.—A girl, aged 16 years, was admitted to Westminster Hospital on Jan. 20th, 1906, complaining of pain on the inner side of the right foot which had troubled her for a year. The pain was at its worst after walking but not severe enough to prevent her from getting about. On examination, on the inner side of the right foot there was a round semi-cystic swelling about one inch in diameter. The highest point of it was one inch below the tip of the internal malleolus, and the lowest point half an inch above the heel. It presented the same physical characteristics as the tumours in the preceding case and was most prominent when the foot was forcibly dorsi-flexed. The swelling was removed and showed the same fatty and vascular character



To illustrate the appearances in Case 2. The position of the lipoma is clearly shown at L., and its relation to the inner longitudinal arch of the foot is evident. I.M., Internal malleolus. A.S., Astragalo-scaphoid joint. The great toe is in a state of temporary spasmodic dorsi-flexion.

was nobody to take his place. The number for May consequently failed to appear at the appointed time, but in due course the editor recovered and being still full of zeal he has now sent out a double number for May and June, 1908, which makes its appearance clad in a brilliant green cover. As may be supposed, the little journal produced under such elementary conditions does not attempt to enter deeply into the more abstruse topics of medicine. On the contrary its object is practical rather than theoretical. As the editor, who is himself a hospital assistant, puts it, the aims of his journal are twofold: to ameliorate the condition of his class and to stimulate their desire for knowledge. Medical papers are sufficiently abundant in India, but many of them consist of little else than advertisements, of a more or less objectionable description, and reproductions of articles from American sources. The *Hospital Assistant*, however, is not one of these. On the contrary, it contains a fair proportion of original matter, while its "*Department of Current Medical Literature*" is recruited for the most part from the European medical press. Hospital assistants, according to their own showing, are not very well treated by the Government which they serve so faithfully. They are silent sufferers, they say, who make no fuss over their wrongs, and the consequence is that they still occupy the same position as regards pay and other advantages which they did 25 years ago. Educational and professional requirements are much higher now than they used to be, but there has been no corresponding increase of remuneration for medical subordinates or improvement in their status. Thousands of human lives are intrusted to the care of hospital assistants all over India, but they remain the only class of subordinate officials who are miserably underpaid and shabbily treated as well in the matter of leave, transfers, allowances, and pensions. After a four years' course of study and the successful surmounting of several searching examinations a hospital assistant receives a starting pay of Rs. 25 per month; nor is that miserable pittance increased until he has spent the better part of his life in a heartbreaking endeavour to keep up a respectable appearance and, it may be, to support a wife and children with totally inadequate means. The foregoing recital of grievances is, of course, an *ex parte statement*, but it seems to be clear that in some respects, and especially as regards pay, the hospital assistants of India are not very well treated by their masters. The cost of living has gone up enormously of late years for all classes, and it would be only just and reasonable to treat this efficient and indispensable body of men with the same liberality that has been accorded to other public servants.

FOREST FIRES.

THE "irony of Providence" has seldom been more vividly in evidence than in these days, when, coincidently with a quickened sense of the need of "re-afforestation" to retrieve the damage wrought by reckless tree-felling, we read of forest fires in both the Atlantic and the Pacific territories involving New England and British America in desolation and ruin. In the Old World the phenomenon has equally been exemplified, though on a scale less widespread and appalling. The centres of antique civilisation—Greece and Italy—have long been the victims of their own improvidence in consuming their timber without concurrent and compensating tree-planting, having drawn down on themselves the Nemesis of injured Nature, whose "balance" they have disturbed by reducing the umbrageous hillsides to prairie, accelerating evaporation by the destruction of its detaining medium, and so incurring the torrential downpour of autumn, the overflow of rivers, and the consequent drought which for nine months of the year converts the watercourses into gravel-pits. So feelingly has the Italian Legislature been impressed with the results of this practice that its official reports and Parliamentary discussions on the theme constitute quite a storehouse of information and suggestion for other nationalities on whom the "retributive justice" of the sylvan deity has fallen less heavily. Rich in illustrations of the causal nexus between short-lived inundation and prolonged drought, these reports and debates are replete with warning as to the changes, meteorological and climatic, which have affected the peninsula disastrously within the memory of men now living. *No medium is more sensitive, more elastic, than the atmosphere; none responds more readily to altered conditions in the earth's crust*, whether these be due to the non-reclamation of waste-lands or to the wholesale destruction of forest growth. The Padre Denza's demonstration of the origin of the sirocco in the Sahara is an example of the former; the change for the worse in the climate of Italy, landward or littoral, is a proof of the latter. Italian meteorologists, indeed, extending their studies beyond their own frontier, see with dismay the annually *increasing* violence of the cyclone, caused, as they hold this to be, by the steady "clearing" of the earth's crust in Transatlantic latitudes, the accelerated evaporation, and the genesis of those "vertiginous storms" which combine to form the "nubifragi" (water-spouts) such as in Tuscany three months ago dealt destruction to the vineyards and olive-groves It is even proposed, in these days of international deliberation, to convene a congress of the Powers with a view to discussing and devising some combined effort to control that denudation of the terrestrial surface which affects the interests and the well-being of all.

> "Tua res agitur cum proximus ardet
> Ucalegon,"

and when the Ucalegontes of the world are realising that their neighbour's "forest fires" menace them individually and collectively, it is high time that common action should be taken to minimise and eventually to remove the "conditions precedent" of the danger thus courted and caused.

SPONTANEOUS EPIPLOPEXY.

EPIPLOPEXY, the production of adhesions between the great omentum and the abdominal wall, is an operation which was devised about 20 years ago by Talma of Utrecht in order to relieve the portal congestion in cases of cirrhosis of the liver attended with ascites by establishing a collateral circulation. In about half the cases the ascites has been cured or relieved. In one case recorded, reported by M. Le Gendre and M. Deglos to the Société Médicale des Hôpitaux of Paris in 1906, on exploratory laparotomy three years after the operation a large venous plexus was found between the abdominal wall and the great omentum which insured a considerable outlet from the portal circulation.[1] At a meeting of the society on July 17th last M. A. Siredey, M. Henri Lemaire, and M. J. Deroye reported a case of cirrhosis of the liver in which the ascites almost disappeared in consequence of the spontaneous establishment of such a collateral circulation. A man, aged 41 years, was admitted into hospital on April 13th, 1908, suffering from right pleural effusion. Paracentesis yielded a litre of pus containing numerous streptococci. It was noticed that the abdominal wall and thorax were covered with large veins running longitudinally and communicating with the epigastric veins below and the axillary and subclavicular veins above. At the level of attachment of the diaphragm were numerous little red vessels like those seen on the surface of a varicose leg. The abdomen was a little flaccid and there were no signs of

---

[1] THE LANCET, Jan. 19th, 1907, p. 180.

Dirty water.—This was drained off by surface drains into the paved gutter of the street except in the case of one regiment where special arrangements had to be made. These short drains ran obliquely and were banked up. The ground around the benches was paved with shingle from the beach and so kept dry. At the bottom of the street at each side two large deep soakpits were dug to take up the excess water. These being in the loam, and measuring each 8 feet by 6 feet by 6 feet deep, had to be pumped out daily, there being practically no absorption. They were covered by improvised wooden covers.

Horse lines.—Special attention was paid to these. They were kept scrupulously clean throughout. The field ambulance horse lines were shifted after seven days, there being insufficient space. Manure tended to accumulate at first. I was unable to find any way of keeping it covered up. It is obvious that all manure in a standing camp should be kept covered up pending removal. The heaps were kept as far as possible from the tents and were cleared away daily. Swarms of small brown flies were always to be seen at these heaps but nowhere else. The almost complete absence of flies was a marked feature of the camp.

Latrines.—The system adopted here was to insist on the men covering their dejecta with earth. The means adopted to secure this were (1) by battalion orders; (2) by policing; (3) by having notice boards in the latrines where they could not help being seen; (4) by having heaps of earth piled up in front of the latrine seats; and (5) by the supply of cheap metal scoops. (The latter are so cheap as not to be worth the removal. The pioneer's spade, if used for this purpose, tends to disappear.) This system when carried out by all ranks acted well. Two battalions were exceptionally good. In them I was well supported by the officers of all ranks, so that the system had a fair trial, and I was quite satisfied with the result. It must be said, however, that if the system is to be relied on all ranks must give their hearty coöperation. Once the habit is acquired the method will be carried out spontaneously. The space allowed for latrines should not be limited. Quicklime is unnecessary; it is not to be depended on and when thrown into latrine trenches indiscriminately is useless. One of the sanitary squad should pay a visit several times daily and any excreta left uncovered should be covered by him with soil.

Urinals.—The pattern adopted was that of a central pit, 2 feet across by 3 feet deep, covered over, and with shallow trenches from 6 to 8 feet long, radiating from the centre like the spokes of a wheel, and with a fall to the pit. These trenches for a regiment of 500 will last over two days. Earth scattered periodically over the edges of the trench and into the trench itself in a thin layer will keep the trench from becoming foul. At the end of this period fresh trenches should be dug in the angles. At the end of the week a fresh urinal should be dug. There should be standing accommodation, allowing 2 feet per man, for from 24 to 30 men to urinate simultaneously. Four trenches should be in use at a time. Observations during the "rush" hour—i.e., before and after parades—showed that for a strength of from 300 to 400 men, this accommodation was the minimum, otherwise men would foul the surrounding ground and the latrine screen. Where possible I arranged that the screens should be kept well clear of the trenches and that the urinal should be separate from the latrine. Some of the units had urine tubs. These were used in addition to the trenches and were emptied into the pits.

Hawkers.—These were not allowed in camp. Various vendors of shell-fish, ice-cream, and fruit congregated outside the camp, out of the jurisdiction of the military police. I visited their barrows occasionally. The shell-fish and ice-cream were of very dubious origin. The fruit sold by local tradesmen I found to be of good quality. One or two cases of gastric trouble attributable to the consumption of shell-fish were reported, and it would have done no harm had samples of these been taken by the local authorities for analysis.

Lectures on sanitation.—These lectures were given by me to all units and were attended by all ranks. They were short and given in simple language, and included such points as fouling the ground, covering the dejecta, clothing, cleanliness, care of the feet, water discipline, and the eating and drinking of unwholesome food and water. I think that these lectures had a good effect. They should not be given in the afternoon when men are tired and tend to fall asleep. More technical lectures on food and meat inspection, infectious disease, contagious disease in animals, &c., were given to the Royal Army Medical Corps and Army Service Corps units.

Bathing parades were held and feet inspections were made. I was struck by the large number of deformed feet amongst the men.

Infectious disease.—One case of suspected enteric fever occurred in the first three days of the camp. The patient had been in contact with cases of enteric fever at his home. He was removed to Dover. His tent was vacated and all bedding, blankets, &c., were disinfected by steam. Contacts were bathed, had fresh clothing issued, and were inspected daily for the rest of the camp. A fresh latrine and urinal were dug and particular attention was paid to see that all excreta were covered. The sanitary arrangements of the regiment where this case occurred demand some mention. The kitchens and ablution benches were placed at the top of the hill on the opposite side from the main street. Surface drains were dug and three large soak-pits into the chalk at different levels. Interceptors filled with straw were dug at the entrance to these pits. The water soaked away rapidly. The straw took up the grease and soap. The pits were used alternately and periodically the sides were scraped down. They lasted well all the camp and no overflow occurred. In the same way all the urine was absorbed by two narrow and deep urine-pits. I was materially assisted by the regimental medical officer and by the quartermaster of this regiment, the 5th Royal West Kent, in carrying out this plan. The latrines and urinals in this case were rather too close to the tents and stores for safety. These officers made it their business to see that the advice of the senior medical officer and myself was acted upon and their assistance was invaluable.

The Cadet Battalion of the Queen's Regiment was encamped at the top of the hill, next to the 5th Royal West Kent Regiment, during the second week. I was afforded the opportunity of planning out sanitary accommodation for them previous to their arrival. In this case the kitchens and ablution arrangements were kept separate. Covered soak-pits with intercepting traps filled with straw were dug. These soak-pits took up and absorbed all the waste water. The straw was burnt in the destructor when necessary and fresh straw put in the traps. These soak-pits lasted throughout the seven days of the training. A destructor was built. Covered refuse barrels were provided and notices were posted at each distinguishing the kind of refuse to be thrown into them. The latrines for the men were dug on the shallow trench pattern, the urinal on the wheel pattern. 15 of the former were dug in two rows measuring 3 feet long, 2 feet deep, and 1 foot across, and with an interspace of 2½ feet. The number using them would be about 200. Toilet paper was supplied in empty coffee tins. Notices were posted up, and scoops and heaps of earth supplied. The company officers were interviewed by me. The result was that this latrine was always clean. A few minutes' work twice a day sufficed to keep the place shipshape. A rail to hold on by was found to be unnecessary. The squatting position across the trench was used. The first series of trenches lasted three days; these were then filled in and fresh ones dug in the interspaces from 2 to 3 feet deep. These lasted the remaining four days and could have lasted a day longer. The deep trench system was used by the officers and non-commissioned officers and was not nearly so satisfactory. This camp was always found to be clean at whatever time it was visited.

I made some observations on the time taken to dig these trenches. One of the field ambulances had pitched a camp on one of the manœuvre areas. I found that three men with spades and picks could dig three of these trenches in half an hour. Given plenty of space and men who can handle spades it is obvious that these shallow trenches involve much less labour and are more satisfactory in every way than the old pattern deep ones. A uniform pattern of latrines and urinals should be used by all ranks. Screens should not be limited in number. Pockets to button up should be made in each screen. Into these the scoops referred to should be placed. There would be little addition to the weight or space when the screen was rolled up and these articles would be on the spot when wanted.

I may add that I am much indebted to Colonel E. Satterthwaite, V.D., the colonel commanding the brigade, for the continuous interest which he took and for the support which he gave me in carrying out my duties.

Gravesend.

appears to be evidence that the selection of patients who are allowed out is not always a judicious one. There are allegations of acts of indecency and of drunkenness on the part of patients which, if true, constitute a gross scandal. There is, we believe, no therapeutic justification for allowing abroad a patient who has so little control over himself that he is likely to behave with impropriety or even with marked eccentricity. Neither can we see any advantage which is likely to accrue to the advanced dement in a walk beyond the asylum grounds. Only too often such a patient is an object of unseemly derision on [illegible] and thoughtless from which he shou[illegible] than to which he should be exposed. That there do exist classes of patients who benefit enormously by occasional and, indeed, sometimes by frequent outings we emphatically affirm, but it is fortunate that the patients likely to be so benefited are the very last to be mistaken by the public for anything but sane, or, at the worst, mildly eccentric. We are of opinion that a large part of the present difficulty arises from the undermanning of the asylums with medical officers. The enormous number of patients renders a proper medical supervision out of the question, and that treatment should be applied to batches of patients without consideration of the individual requirements of the case is, of course, radically improper. But we fear that the day is still far off when the medical officer of an asylum will no longer be regarded as a mere keeper of lunatics and will be recognised as practising in one of the very highest branches of our profession. Perhaps, too, our system would be none the worse if the official guardians of the insane, the Commissioners in Lunacy, placed a little more confidence in the medical officers. To the requirements of the Commissioners this despatch of large unassorted parties of patients on walking parties is a direct response, even, as we have recently pointed out, as the neglect of certain therapeutic measures is seemingly due to a dislike on their part of finding patients in bed. We fear that so far as Epsom is concerned the initial error of placing so many large asylums in close contiguity cannot be rectified but we have little doubt that the more glaring nuisances may be abated.

THE EPIDEMIC OF CHOLERA IN RUSSIA.

RECENT reports from Russia do not indicate a diminution in the epidemic of cholera but it is not at present showing any likelihood of attaining the terrible proportions of the epidemic which ravaged that unhappy country in 1902. The medical authorities in St. Petersburg appear to be making strenuous efforts to cope with the situation in the face of a lamentable state of sanitary deficiency in the poorer quarters of that city. So far as regards London we understand that the London County Council is taking measures similar to those which proved quite effective when cholera broke out on the waterways of the Oder and Vistula in 1905. The main feature is a cooperation of the Metropolitan Asylums Board with the London County Council, the former body undertaking to receive persons suffering from actual or suspected cholera, and the latter to provide accommodation when necessary for persons who may have been in contact with cases of the disease. Great attention is being paid by the Council to the verification of addresses given by immigrants, whose movements are traced so long as they remain in London, the owners of the premises where they lodge being responsible under penalty for the notification of any change in their addresses. The medical officers of health in the various metropolitan and other boroughs in which they are lodging are kept informed of such movements. These precautions were satisfactory to the Local Government Board in 1905 and were fully justified by their success. There is scarcely need for the Board to impress the necessity of close watchfulness upon the various port authorities throughout the kingdom, for their constant and great responsibility as the country's first line of defence against disease becomes especially apparent at times such as the present. We trust that better reports from Russia may speedily arrive to remove finally any public anxiety as to the chances of cholera invading Great Britain. Our Paris correspondent sends an interesting account of the measures which are being taken in France to safeguard that country against the entry of the disease.

SOME AMERICAN DRUGS.

MANY plants are used for medicinal purposes in the United States which have not yet been used to any great extent in other countries. Owing to the fact that many drugs of American origin are being largely employed in Europe, notably hydrastis, senega, gelsemium, podophyllum, and euonymus, to name only a few examples, it is of interest to refer to some popular drugs indigenous to America which are described by Miss Alice Henkel in Bulletin No. 107, Bureau of Plant Industry of the United States Department of Agriculture. Wild turnip, arisæma triphyllum, is an acrid plant, of which the corm is used as a stimulant, diaphoretic, expectorant, and irritant. It was official in the United States Pharmacopœia from 1820 to 1870. The root of an evil-smelling herb known as skunk cabbage, spathyema fœtida, was official in the United States Pharmacopœia from 1820 to 1880. It has an objectionably fœtid odour and a sharp acrid taste and is used in affections of the respiratory organs, and in nervous disorders, rheumatism, and dropsy. Skunk cabbage loses its odour and acridity with age and should not be kept longer than a year. Beth root, trillium erectum, has a slight odour and when chewed causes a flow of saliva. The taste is at first sweetish and astringent and afterwards bitter and acrid. It was much esteemed among the Indians and early settlers. It is now used for its astringent, tonic, alterative, and expectorant properties. The root of lady's slipper, cypripedium pubescens, a beautiful member of the orchid family, is official in the United States Pharmacopœia. It is used as an antispasmodic and nerve tonic for the same purposes as valerian. Another orchid, crawley root, corallorhiza odontorhiza, is used as a sedative and in febrile conditions. It is said to be an effective diaphoretic. Canada snake root, ascarum canadense, which is used as an aromatic, diaphoretic, and carminative, was official in the United States Pharmacopœia until 1880. The yellow dock, rumex crispus, is largely used with other species of dock for "purifying the blood" and in the treatment of skin diseases. The root of pokeweed, phytolacca decandra, is used as an alterative, also to relieve pain and allay inflammation. It has purgative and emetic properties. The fully matured berries are also employed in medicine. The roots and leaves of soapwort, saponaria officinalis, have tonic, alterative, and diaphoretic properties. The Indians and early settlers esteemed the little root of goldthread, coptis trifolia, as a remedy for ulcerated mouth, and it is still used as a mouthwash or gargle and as a bitter tonic. It was official in the United States Pharmacopœia from 1820 to 1880. Oregon grape-root, berberis aquifolium, has long been used as a tonic and alterative and is now official in the United States Pharmacopœia. Blue cobosh, caulophyllum thalictroides, is used as a demulcent, antispasmodic, emmenagogue, and diuretic. It was official in the United States Pharmacopœia for 1890. Twinleaf, Jeffersonia diphylla, is used as a diuretic, alterative, antispasmodic, and diaphoretic. Large doses are said to be emetic and smaller doses tonic and expectorant. The root of Canada moonseed, menispermum canadense, was

Dirty water.—This was drained off by surface drains into the paved gutter of the street except in the case of one regiment where special arrangements had to be made. These short drains ran obliquely and were banked up. The ground around the benches was paved with shingle from the beach and so kept dry. At the bottom of the street at each side two large deep soakpits were dug to take up the excess water. These being in the loam, and measuring each 8 feet by 6 feet by 6 feet deep, had to be pumped out daily, there being practically no absorption. They were covered by improvised wooden covers.

Horse lines.—Special attention was paid to these. They were kept scrupulously clean throughout. The field ambulance horse lines were shifted after seven days, there being insufficient space. Manure tended to accumulate at first. I was unable to find any way of keeping it covered up. It is obvious that all manure in a standing camp should be kept covered up pending removal. The heaps were kept as far as possible from the tents and were cleared away daily. Swarms of small brown flies were always to be seen at these heaps but nowhere else. The almost complete absence of flies was a marked feature of the camp.

Latrines.—The system adopted here was to insist on the men covering their dejecta with earth. The means adopted to secure this were (1) by battalion orders; (2) by policing; (3) by having notice boards in the latrines where they could not help being seen; (4) by having heaps of earth piled up in front of the latrine seats; and (5) by the supply of cheap metal scoops. (The latter are so cheap as not to be worth the removal. The pioneer's spade, if used for this purpose, tends to disappear.) This system when carried out by all ranks acted well. Two battalions were exceptionally good. In them I was well supported by the officers of all ranks, so that the system had a fair trial, and I was quite satisfied with the result. It must be said, however, that if the system is to be relied on all ranks must give their hearty coöperation. Once the habit is acquired the method will be carried out spontaneously. The space allowed for latrines should not be limited. Quicklime is unnecessary; it is not to be depended on and when thrown into latrine trenches indiscriminately is useless. One of the sanitary squad should pay a visit several times daily and any excreta left uncovered should be covered by him with soil.

Urinals.—The pattern adopted was that of a central pit, 2 feet across by 3 feet deep, covered over, and with shallow trenches from 6 to 8 feet long, radiating from the centre like the spokes of a wheel, and with a fall to the pit. These trenches for a regiment of 500 will last over two days. Earth scattered periodically over the edges of the trench and into the trench itself in a thin layer will keep the trench from becoming foul. At the end of this period fresh trenches should be dug in the angles. At the end of the week a fresh urinal should be dug. There should be standing accommodation, allowing 2 feet per man, for from 24 to 30 men to urinate simultaneously. Four trenches should be in use at a time. Observations during the "rush" hour—i.e., before and after parades—showed that for a strength of from 300 to 400 men, this accommodation was the minimum, otherwise men would foul the surrounding ground and the latrine screen. Where possible I arranged that the screens should be kept well clear of the trenches and that the urinal should be separate from the latrine. Some of the units had urine tubs. These were used in addition to the trenches and were emptied into the pits.

Hawkers.—These were not allowed in camp. Various vendors of shell-fish, ice-cream, and fruit congregated outside the camp, out of the jurisdiction of the military police. I visited their barrows occasionally. The shell-fish and ice-cream were of very dubious origin. The fruit sold by local tradesmen I found to be of good quality. One or two cases of gastric trouble attributable to the consumption of shell-fish were reported, and it would have done no harm had samples of these been taken by the local authorities for analysis.

Lectures on sanitation.—These lectures were given by me to all units and were attended by all ranks. They were short and given in simple language, and included such points as fouling the ground, covering the dejecta, clothing, cleanliness, care of the feet, water discipline, and the eating and drinking of unwholesome food and water. I think that these lectures had a good effect. They should not be given in the afternoon when men are tired and tend to fall asleep. More technical lectures on food and meat inspection, infectious disease, contagious disease in animals, &c., were given to the Royal Army Medical Corps and Army Service Corps units.

Bathing parades were held and feet inspections were made. I was struck by the large number of deformed feet amongst the men.

Infectious disease.—One case of suspected enteric fever occurred in the first three days of the camp. The patient had been in contact with cases of enteric fever at his home. He was removed to Dover. His tent was vacated and all bedding, blankets, &c., were disinfected by steam. Contacts were bathed, had fresh clothing issued, and were inspected daily for the rest of the camp. A fresh latrine and urinal were dug and particular attention was paid to see that all excreta were covered. The sanitary arrangements of the regiment where this case occurred demand some mention. The kitchens and ablution benches were placed at the top of the hill on the opposite side from the main street. Surface drains were dug and three large soak-pits into the chalk at different levels. Interceptors filled with straw were dug at the entrance to these pits. The water soaked away rapidly. The straw took up the grease and soap. The pits were used alternately and periodically the sides were scraped down. They lasted well all the camp and no overflow occurred. In the same way all the urine was absorbed by two narrow and deep urine-pits. I was materially assisted by the regimental medical officer and by the quartermaster of this regiment, the 5th Royal West Kent, in carrying out this plan. The latrines and urinals in this case were rather too close to the tents and stores for safety. These officers made it their business to see that the advice of the senior medical officer and myself was acted upon and their assistance was invaluable.

The Cadet Battalion of the Queen's Regiment was encamped at the top of the hill, next to the 5th Royal West Kent Regiment, during the second week. I was afforded the opportunity of planning out sanitary accommodation for them previous to their arrival. In this case the kitchens and ablution arrangements were kept separate. Covered soak-pits with intercepting traps filled with straw were dug. These soak-pits took up and absorbed all the waste water. The straw was burnt in the destructor when necessary and fresh straw put in the traps. These soak-pits lasted throughout the seven days of the training. A destructor was built. Covered refuse barrels were provided and notices were posted at each distinguishing the kind of refuse to be thrown into them. The latrines for the men were dug on the shallow trench pattern, the urinal on the wheel pattern. 15 of the former were dug in two rows measuring 3 feet long, 2 feet deep, and 1 foot across, and with an interspace of 2½ feet. The number using them would be about 200. Toilet paper was supplied in empty coffee tins. Notices were posted up, and scoops and heaps of earth supplied. The company officers were interviewed by me. The result was that this latrine was always clean. A few minutes' work twice a day sufficed to keep the place shipshape. A rail to hold on by was found to be unnecessary. The squatting position across the trench was used. The first series of trenches lasted three days; these were then filled in and fresh ones dug in the interspaces from 2 to 3 feet deep. These lasted the remaining four days and could have lasted a day longer. The deep trench system was used by the officers and non-commissioned officers and was not nearly so satisfactory. This camp was always found to be clean at whatever time it was visited.

I found that three men with spades and picks could dig three of these trenches in half an hour. Given plenty of space and men who can handle spades it is obvious that these shallow trenches involve much less labour and are more satisfactory in every way than the old pattern deep ones. A uniform pattern of latrines and urinals should be used by all ranks. Screens should not be limited in number. Pockets to button up should be made in each screen. Into these the scoops referred to should be placed. There would be little addition to the weight or space when the screen was rolled up and these articles would be on the spot when wanted.

I may add that I am much indebted to Colonel E. Satterthwaite, V.D., the colonel commanding the brigade, for the continuous interest which he took and for the support which he gave me in carrying out my duties.

Gravesend.

himself or the public if he be allowed to drive an automobile." He would have the medical examination repeated at every second or third renewal of the licence. We should welcome the adoption of such a regulation as affording an ideal precaution but are not at all sure that it would yet be tolerated. It would be wise, however, for private employers to protect themselves by insisting on an authoritative certificate of health and fitness from those to whom they intrust their lives and limbs. The danger is by no means an imaginary one. There is now a very large body of men employed in driving motor-cars and it is almost certain that some amongst them are suffering from serious and perhaps unsuspected disease. A case is within our knowledge where a chauffeur who had suffered from sudd[illegible] syncopal and epileptic attacks proved to [illegible] a pronounced "Stokes-Adams syndrome." [illegible] of some ethical delicacy as to whether his employers should be informed of the gravity of the man's condition. Possibly unconsciousness or other sudden illness of a chauffeur might account for certain unexplained motor-car accidents. The case of the cocaine-taker is, we hope, unique, for the victim of the most dangerous of all drug habits would probably soon prove himseif so unfit to drive a motor-car, both mentally and physically, that the most casual employer could hardly fail to discharge him. The condition of the prisoner was described as "shocking" by the magistrate, and it is difficult to imagine with whom he had obtained employment.

THE GASTRO-INTESTINAL GANGLIONIC NERVOUS SYSTEM.

IN the Section of Physiology at the recent meeting of the British Association Sir James Grant, well known alike as geologist, physician, and man of affairs in Canada, drew attention to the remarkable effects in improved digestion and general restoration of health which he had observed clinically in a number of cases as the result of the application of electricity daily for two or three weeks over the abdomen by means of the instrument known as the "neurotone," of which he demonstrated the mode of use. He also gave the details of several clinical cases. To explain these effects he considered that the neurotone current applied to the abdominal ganglionic centres brings about a change in the axis-cylinders of the nerves supplying the intestines, thus restoring imperfect physiological continuity and re-establishing the free transmission of nervous impulses, with the result that digestion and general health are greatly improved. He believed that in many cases where there was no organic disease years might be added to life by the treatment which he had described. This, perhaps a little unguarded, expression of opinion led at once to the discovery by certain daily papers that Sir James Grant had unfolded the secret of the prolongation of life, a statement which lost no force by the fact that the distinguished physician's remarks had been made at a meeting of the British Association for the Advancement of Science. As many of our readers, like ourselves, may have been asked what Sir James Grant's views were we publish this brief note on his paper, but we cannot inform them where the instrument can be purchased.

DIAGNOSIS OF ROTHELN BY BLOOD COUNTS.

DURING an epidemic of "measles" occurring amongst the men in an Argentine cavalry regiment, which Dr. Javier Ponce De Leon was able to show was one of rötheln only, he made use of blood counts as one method of diagnosis. He and Dr. Pedro Labaqui have studied this method in other epidemics also and find that in rotheln there is a diminution of the leucocytes, more especially during the eruptive period, and that the number of mononuclear corpuscles is increased, the maximum occurring during th eruptive period. Dr. De Leon also found that eosinophi corpuscles decreased slightly in number during the eruptiv stage and slowly increased as convalescence progressed. H suggests that in doubtful cases a single drop of bloo treated by Hoffmann's stain and then by hæmatin and eosi will show a much larger number of mononuclear bodies tha would be seen in measles or scarlet fever, and thus will form a ready means of diagnosis.

THE MEDICAL AUTHORSHIP OF THE THIRD GOSPEL.

"REMORSELESS [illegible] pon of the Highe[illegible] its [illegible] That it can be [illegible] equal if not greater effect on the side of the defence is also manifest—nowhere more clearly than in the literature which has accumulated round the question as to who wrote the Third Gospel. That that book, pronounced by Renan to be "the loveliest ever written," had for its author a physician of Gentile, probably Greek, origin, whose name was Luke, was accepted not only by early Christians but by mediæval and modern divines down to the middle of last century, when the Tubingen School may be said to have brought it into court. Counsel *pro et contra* have since been heard—

> "Praeconis ad fastidium,"

and the summing up and verdict, for which the world has been waiting, may now be said to have been given, and that in favour of the traditional view. Professor Harnack demonstrates that those who collected the Gospels into a quartette shortly after the appearance of the Fourth Gospel gave the Third the title which it afterwards bore without challenge —to wit, "According to Luke (κατὰ Λουκᾶν)." "Anonymous compilations," he says, "in the course of tradition easily acquire some determining name, and it is easy to imagine an author writing under a pseudonym. But in the case of a writing determined by a prologue and a dedication we require some very definite reasons for a substitution of names, especially when this is supposed to occur only one generation after the date of publication" ("Lukas der Arzt," p. 2). The tradition, "so unvarying and so constant from the first, and becoming vocal and explicit by the time of Irenæus," adds Dr. Thomas Nicol, "is to be explained only by the fact that St. Luke was the writer. The book was ascribed to him, just as the 'Annals' are ascribed to Tacitus and 'Romeo and Juliet' to Shakspere." The able and accomplished theologian just named, whose "Baird Lectures"[1] delivered from the chair of Biblical Criticism in the University of Aberdeen last year contain a luminous exposition of the whole question, shows further that the Third Gospel and the Acts of the Apostles are from the same pen. "The language, style, and literary arrangement are identical. Characteristic words and expressions are found in both. The author of either book has skill in writing Greek and the Septuagint was *his* Bible more than St. Paul's. Again, assuming that the Gospel and the Acts are by the same hand, we learn from the 'we-sections' of the Acts that he was a companion in travel and a fellow-labourer of St. Paul. It is not enough to say that these 'we-sections' are interpolations or portions of a diary of travel belonging to some other person. The literary characteristics, the miraculous incidents, and other special phenomena show them to be of exactly the same texture as the rest of the work. Finally, the crowning proof of identity which fixes the authorship unmistakably upon Luke, the 'Beloved Physician,' is the indication of medical interest and the employment of medical phraseology which runs to the clot, and through this opening he tells us that the clot will extrude itself. He has performed this operation on three cases. A very useful chapter is that in which the technique of intracranial operations is described. The whole article extends to 276 pages and is a complete treatise on the surgery of the head.

---

[1] The Four Gospels in the Earliest Church Histories. Blackwood, Edinburgh and London, 1908.

Dr. G. Wyllys Andrews of Chicago has contributed the section on the *Surgery of the Neck*; it is fairly inclusive, but it does not contain the surgery of the thyroid gland or the larynx or œsophagus. It deals with branchial cysts, torticollis, the lymphatic glands and blood-vessels of the neck, and the salivary glands. It contains a good account of the dissection of the glands of the neck in cases of carcinoma.

Dr. Albert Kocher has supplied the chapter on the Diseases of the Thyroid Gland. The most noticeable point is the strong approval expressed in favour of the surgical treatment of Graves's disease. He mentions that Professor Theodore Kocher has performed the operation of thyroidectomy 200 times for this condition, that the mortality has been 4·5 per cent., and that in 85 per cent. of the cases the patient has completely recovered. In severe cases Dr. A. Kocher considers that it is advisable to perform one or two preliminary ligations of the superior thyroid artery. The operation is, in his opinion, indicated in all cases that do not present degeneration of the heart muscle with irregular pulse, low blood pressure, or periodical attacks of what has been called "delirium cordis." Many surgeons in this country have hitherto objected to partial thyroidectomy for Graves's disease, but the opinion of Professor Kocher should count for much. No new ideas are expressed in the diagnosis or treatment of goitre, but an excellent account of this condition is given. Unfortunately, throughout the whole chapter the word "struma" is employed in the German meaning of the word; it is a pity to attempt to introduce this meaning into English, it can only lead to confusion.

Dr. Harmon Smith of New York has written the chapter on the Surgery of the Nose and its Accessory Sinuses. He considers that it is safest when using paraffin injections for a "saddle nose" to inject the paraffin in the solid form. A very good account is given of the surgery of the frontal sinuses.

The Surgery of the Larynx and Trachea is described by Dr. George Emerson Brewer of New York. He gives some very effective illustrations of the method of using Killian's bronchoscope. He has also supplied the account of the Surgery of the Thorax. We cannot agree with the writer when he says that in cases of tuberculous empyema it is better to wait until spontaneous rupture is imminent. The tuberculous cases require greater care to prevent septic infection but the results of timely careful operation are better than would be imagined from the account given here. In the description of the treatment of hydatid cyst of the lung aspiration is condemned on account of the danger of infecting the pleura, but the greatest danger comes from the risk of rapid death from rupture of the cyst into a bronchus at the moment of aspiration. Very brief accounts are given of the various forms of thoracoplasty; it would have been well to treat this subject more fully. The surgery of the chest is yearly becoming of greater importance and it seldom receives adequate treatment in text-books.

Dr. J. M. T. Finney of Baltimore gives a satisfactory account of the Surgery of the Breast, especially of its most important part the operation of excision of the breast for carcinoma. Mr. Edmund Owen writes very clearly on the Surgery of the Mouth, Teeth, and Jaws. We quite agree with him that harelip pins should never be used for harelip. He speaks favourably of Brophy's operation for cleft palate in small children. The method is hardly employed in this country as much as it deserves. Dr. J. Chalmers Da Costa of Philadelphia is responsible for the chapter on the Surgery of the Tongue. For the removal of small masses of malignant disease affecting the tongue he does not consider it necessary to remove the whole tongue, for, as he points out, local recurrence is much rarer than recurrence in the glands. He favours removal of the tongue through the mouth and then, after a short interval, removal of all the lymphatic glands of the neck on the same side and a little later on the opposite side.

The remainder of the book is devoted to abdominal surgery, but includes the œsophagus. Dr. J. C. Munro of Boston writes on the Technique of Abdominal Surgery, on the surgery of the abdominal wall and of the peritoneum and the retroperitoneal space. He is very much in favour of the semi-sitting or Fowler position for the limitation of peritoneal infection. He insists on the importance of the fact that the diaphragmatic peritoneum has much greater absorbing power than the peritoneum lining the pelvis. Dr. G. Gottstein of Breslau is responsible for the article on the Surgery of the Œsophagus, and it is very good indeed; it is especially full in the description of the methods of examination. Mr. A. W. Mayo Robson has written the account of the Surgery of the Stomach. His views on gastric surgery are so well known in this country that there is no need to discuss them here. He prefers the posterior operation for gastro-enterostomy and describes clearly the exact method which he prefers. He finds the "bobbin" which he devised very useful and he still uses it. Dr. W. J. Mayo and Dr. C. H. Mayo have written the chapter on the Surgery of the Liver, the Gall Bladder, and the Biliary Ducts, and it is hardly necessary to say that it is very good. The authors are not in favour of removing the gall-bladder in ordinary cases of gall-stones, though they acknowledge that it is as obsolescent as the appendix. They prefer the vertical incision of Bevan for exposing the gall-bladder and bile-ducts, enlarging it towards the middle line above and outwardly below if more room is needed. Mr. B. G. A. Moynihan is responsible for the chapter on the Pancreas and on the Spleen. The most important portion of the former chapter is that devoted to pancreatic cysts. In the case of wounds of the spleen Mr. Moynihan advises that the wound should be sutured when possible and that excision should only be performed when suture is impossible.

All the articles are adequately illustrated and a full index is appended.

Contributions to the Study of the Early Development and Imbedding of the Human Ovum. I. An Early Ovum Imbedded in the Decidua. By THOMAS H. BRYCE, M.A., M.D. Edin., Lecturer in Anatomy, University of Glasgow; and JOHN H. TEACHER, M.A., M.D. Glasg., Lecturer on Pathological Histology, University of Glasgow. *II. An Early Ovarian Pregnancy.* By THOMAS H. BRYCE, JOHN H. TEACHER, and JOHN M. MUNRO KERR, M.B., C.M. Glasg., Obstetric Physician to the Maternity Hospital and Gynæcologist to the Western Infirmary, Glasgow. With ten plates and 12 figures in the text. Glasgow: James Maclehose and Sons. 1908. Pp. 93. Price 12*s.* 6*d.* net.

THE opportunities for obtaining an early human ovum in a condition fit for investigation occur of necessity but rarely and Dr. J. H. Teacher and Dr. T. H. Bryce are to be congratulated on their good fortune in this respect. They have been able to examine carefully what is perhaps the very youngest human ovum which has been described, and the results of their work they have published in a monograph which also contains a description of a specimen of early ovarian pregnancy removed by operation by Dr. Munro Kerr. While it is true that recent work in comparative *shown by experiment* to be due to the fact that in presence of certain bacilli of the Bulgarian and other Oriental milk ferments they cease to multiply after a time. In Eastern Europe the milk of the cow, ass, goat, and buffalo is used to make various articles of food with ferments which contain, besides the useful Bulgarian *lactic-acid* bacillus, great numbers of objectionable yeasts, butyric acid-forming bacilli, and even dangerous pathogenic organisms, and yet the longevity and strength of these people are remarkable. It is desirable, before making empirical use of the lactic ferments or pure cultures of special bacilli in the treatment of diseases of the gastro-intestinal tract, that the practitioner [illegible] able to reason out for himself why lactic ferments [illegible] results rather than that he should lean on th[illegible] findings *of others, and the* [illegible] e question will explain in a great measu[illegible]

The formation of lactic acid must o[illegible] expense of nutritive material acting as [illegible] which *the* bacteria *proliferate*, whet[illegible] or within the human *alimentary tract. Pasteur in* 1859 showed that a diplococcus caused the *souring of milk* when exposed to the air by the transformation of the sugar (lactose) into lactic acid; later, however, he found this property *to* be shared by an *indefinite* number of micro-organisms, since hexoses are broken down by this process *of* fermentation into *the* [illegible] y lactic acid. The *staphylococcus* [illegible] albus, bacterium termo, bacillus subtilis, bacillus coli communis, bacillus putrificus, sarcina ventriculi, oidium lactis, bacillus pyocyaneus, bacillus lactis aerogenes, and hundreds of others change the chemical arrangement of the atoms in a molecule of *organic matter, producing* various odours, *colours, aromatic substances, modifying* their physical properties partially or entirely and giving rise to lactic acid amongst the other products. We have examples of these changes in cheese, koumiss, &c. In the therapeutic administration of *lactic*-acid-forming bacteria, however, we are *chiefly concerned with those which prevent secondary* decomposition of the proteids of food, and the whole question of their value depends on this point which has not in the writer's opinion been insisted upon sufficiently. We know how complicated the composition of food is; *our* knowledge of the chemistry of the proteids is *still* very incomplete, but we know *that* albumins and albuminoids are made up of complex groups derived from the benzine ring, carbohydrates, amides, and groups in which the elements sulphur, phosphorus, and nitrogen have an important place, and that under the influence of the various micro-organisms a process of hydration, dehydration, and splitting up of these groups into simpler groups occurs. The slow process by which our knowledge *of lactic ferments* has been evolved has become further complicated by the facility with which various culture media modify the products of fermentation.

In order to reach an intelligent classification necessary *to* this question we must understand that a true lactic acid bacillus exists only in theory, since at least 150 species of the lactic-acid-forming type are known which give very nearly the theoretical yield of lactic acid from a given amount *of saccharine matter* under suitable *conditions*, which will prevent the lactic acid formed from arresting the fermentation, just as the ethylic alcohol formed by yeast arrests fermentation of a saccharine solution. The *living* cells *of* these bacilli *are* unable *to resist* indefinitely the anti-fermentative action *of* the acid, which is precisely the preservative of sourkrout, butter-milk, &c.

Certain Bulgarian bacilli found in the butter-milk *of* Eastern Europe, *however, are not only the most active yet* studied, but they resist longer the increasing amount of lactic acid produced through their agency; hence the Bulgarian bacilli are usually preferred for therapeutic purposes. Most of the lactic ferments belong to the class known as para-lactic and the pseudo-lactic ferments. The pseudo-lactic ferments are those which give rise to comparatively little acid but give the aromatic and *peptonising products to* cheese, *modify sourkrout*, and other preserved *vegetables* and prevent their putrefaction. The para-lactic ferments are those which attack other substances besides the carbohydrate groups and decompose saccharine *fluids with* the production of *alcohol*, acetic, *formic, malic*, and other acids with variable amounts *of lactic acid*. These para-lactic and pseudo-lactic ferments should not predominate in those employed in the treatment of disease, and preference should be given to pure cultures of bacilli which give rise to little else but lactic acid. It is unnecessary to discuss fully the stereo-chemistry of the varieties of lactic acid *formed* by these bacilli, although it has a *somewhat direct* bearing on the question, since the various lactic acid *bacilli give rise* to dextro-, lævo-, inactive, &c., lactic acid according to the culture media employed. We can understand therefore how condition must of necessity be modified in the intestinal tract by the quality of the food ingested. The best clinical *data*, therefore, *will be obtained* when [illegible] lerations *are* taken into account, and from such [illegible] alone can practical deductions be obtained. For [illegible], the bacillus coli communis gives rise to inactive lactic acid with lævulose, while with glucose we obtain a *dextro-lactic acid. Kayser, moreover, has shown that the* presence or absence of peptone affects the *proportions of the* acids formed. Since the lactic ferments act best on the carbohydrates in the presence of the peptones derived from proteids ingested, and secondary changes of these peptones are prevented by the lactic acid *bacilli*, we may *hope for a* scientific solution *of the problem of prolonging life by a study* of these conditions. There appears to be no doubt that while saccharine matter is essential to the life of the lactic acid bacilli these bacilli are *also able to* utilise, *partially* at least, the carbohydrate groups of the proteids, and this is the most reasonable explanation of the prevention *of* putrefaction which we recognise by the presence of indicanuria. That the proteids are broken up by *these lactic acid bacilli* is proved by the fact that the casein of *milk* is peptonised to the extent of 38 per cent. and that we obtain 68 per cent. of the albuminoid phosphorus as soluble calcium phosphate by *their action* on milk.

By the power of a lactic ferment we do not mean merely the quantity of lactic acid produced but the capacity of the living cell to resist the action of the acid. The therapeutic value of lactic acid *bacilli* therefore must not be *considered from the standpoint of* lactic-acid production only. We realise this better when we consider that the proliferation of new cells is effected by the conversion of sugar and that the conversion of this saccharine matter cannot *serve two purposes* at the same *time—i.e., furnish* new cells and lactic acid from the *same* material. Briefly, therefore, *and* without *entering* into the detailed bacteriological considerations of Rist and Khoury, Foucard, Metchnikoff, Massol, Duclaux, *Maze*, Herter, Cohendy, Dybowski, and other investigators who have foreshadowed the clinical findings of Brudzinsky, Tissier, Combe de Lausanne, Hayem, Bouchard, *Beidenham*, Morax, Hoppe-Seyler, Ewald, Hershler, Stern, and numerous authorities, there is good ground for using lactic acid bacilli either in the form of butter-milk or in the dry form of the bacilli themselves in order to prevent, or at least to *diminish*, intestinal *intoxications and the formation of such products of secondary fermentation* as give rise to tyrosin, the conjugated etherial sulphates, and xanthin compounds in excess. Pure cultures of desirable bacilli can be isolated from the Bulgarian ferments and *not only resist gastric digestion and reach* the *intestine alive but proliferate* freely and establish themselves as a part of the intestinal flora by adapting themselves to the more or less anaerobic environment and thrive in the culture media provided by *ordinary food*. These bacilli prevent the breaking-up of the peptone *into excremental products* which diminish the *amount of* nutritive *material* required for the rebuilding of the sero-*albumins* and sero-*globulins* which are elaborated by the *epithelial* cells of *the* villi during the passage of the peptones to the portal vein. The mere splitting-up of the sugar *into lactic acid* is no advantage, *since* lactic *acid* is eliminated chiefly as carbonic acid and water. *The useful* rôle of the lactic acid bacilli therefore appears to consist in preventing changes in the proteids beyond a certain point. As long *as there is* a supply of saccharine material *the bacilli multiply rapidly*, and once *established as a part* of the intestinal flora they counteract the action of such bacteria as the colon bacillus which splits up the proteids beyond the desired *limit, with* production of toxins, gases, &c., *and diminishes the* amount of nutrition supplied *to the blood*. Laboratory experiments have been confirmed by clinical observations showing that the lactic bacilli once established within the *alimentary* canal prevent putrefaction and that this *only begins* again when the *lactic acid* bacilli die and salicylic acid, as it is very unirritating to the kidneys. For injections he prefers a ½ per cent. solution of protargol. The treatment of chronic urethritis is given fully and the author speaks highly of Goldschmidt's urethroscope which was introduced last year. Several chapters are devoted to the complications of gonorrhœa, and for gonorrhœal rheumatism he advises the employment of the hyperæmic treatment of Bier. A valuable chapter is that on the question of marriage for patients who have lately suffered from gonorrhœa. The author maintains that even if no gonococci can be found the presence of pus cells in the "threads" justifies the suspicion that the gonococcus is lurking somewhere in the urethra.

The Physiology of Alimentation. By Dr. MARTIN H. FISCHER, Professor of Pathology in the Oakland College of Medicine, U.S.A. London: Chapman and Hall, Limited; New York: John Wiley and Sons. 1907. Pp. 348. Price $2, or 8s. 6d. net.

THIS work—and it is an excellent one—is not a complete review of the physiology of the alimentary tract; it is rather a series of monographs dealing with various phases of physiology and embodying the more modern physiological investigations on the subjects with which it deals. Its scope will be best understood by grouping the subjects discussed—viz., the mechanical phenomena of alimentation; the juices poured out upon the food and their chemical constituents; ferments and fermentations; the actions of enzymes and bacteria found in the human alimentary tract; regulation of the salivary, gastric, pancreatic, biliary, and intestinal secretions; and the alimentary canal as an absorptive and excretory organ. A very full and interesting account is given of the movements of the stomach and intestines as revealed by the x rays and several full-page x ray photographs by Cannon of the movements of the food in the intestine are reproduced. The intestinal movements are usually classified as swaying or pendular and peristaltic. The investigations of Cannon, however, have shown that those known as "rhythmic segmentation" movements are the most common. Cannon has calculated that a slender string of food may commonly undergo division into small segments more than a thousand times without changing its place in the intestines. The purpose subserved by these movements is obvious, for in the large intestine the commonest movement is antiperistalsis—i.e., the contents in the middle of the cæcum are moved towards the stomach and away from the rectum. There is a full discussion on the various conditions and mental states which influence intestinal movements and a final chapter deals with saline cathartics.

The new nomenclature is adopted for the naming of ferments—i.e., adding the ending *ase* to the root of the Latin or Greek name of the substance upon which the ferment acts—e.g., amylase and lactase; for pepsin we have acid-proteinase and for trypsin alkali-proteinase, while for the ferment discovered by Weinland, which prevents the proteolytic ferments from acting on intestinal worms, and it may be on the walls of the intestine itself, we have the term anti-proteinase; erepsin becomes protease and invertin sucrase; the ferment which splits up arginin into ornithin and urea is arginase, and so on. The chapter on ferments and fermentations is excellent, and in it are set forth the views of Ostwald and Cohen. A ferment does not initiate a chemical reaction but only alters its velocity, so that in infinite time the amount of chemical change brought about by a ferment is independent of the concentration of the ferment. The ferments are usually characterised by a great sensitiveness to comparatively low temperatures. The reactions which are catalysed by a ferment are rarely, if ever, complete, unless the products of the reaction are removed as soon as formed. The reason for the incompleteness of the chemical reaction lies in the fact that "the ferment is continually reforming from the products of the reaction, the substance or substances with which the ferment was mixed originally." This *reversibility* of the action of an organic ferment is one of its fundamental characteristics. A full account is given of the specific actions of the several alimentary ferments. There is an interesting account of the views of Conradi and Loevenhart on the coagulation of milk (p. 117). The views of Emil Fischer and Abderhalden on the polypeptides and the reconstruction of the protein molecule are discussed and there is a valuable section on the old question as to why the alimentary canal does not digest itself, a question as old as the one propounded by the veteran cynic as to the universal solvent:—What kind of a vessel will be needed to hold it?

In the chapters devoted to regulation of the alimentary secretions naturally full attention is given to the work of Pawlow, Bayliss and Starling, Delezenne, and others. The chapters on absorption and excretion are particularly interesting and suggestive; for they deal with membranes, permeable and semi-permeable, van't Hoff's laws of osmotic pressure, lipoidal absorption, and Overton's work on this subject.

We have said enough to show how interesting, instructive, and useful this small but comprehensive work is. We commend it most cordially and with perfect assurance as to its value to the advanced student of medicine and physiology, as well as to practitioners of medicine.

LIBRARY TABLE.

Die Lehre von der Krebskrankheit von den ältesten Zeiten bis zur Gegenwart. (*The Study of Cancer from the Earliest Times up to the Present*). By Sanitätsrat Dr. JACOB WOLFF, of Berlin. With 52 figures in the text. Jena: Gustav Fischer. 1907. Pp. 747. Price 20 marks.—The thoroughness of this historical study of malignant diseases is evident when we mention that the author commences with the Ebers Papyrus which is supposed to have been written about 1500 B.C. The history is continued through the succeeding ages until it reaches the Renaissance; from the Renaissance the author takes the chief countries in turn and treats of the work on cancer which has been accomplished in each. Then he considers the various theories which have been held to explain malignant disease. The lymph theory was accepted mainly during the eighteenth century. Then arose the cellular theory, and in various modified forms that theory exists to-day. Cohnheim's embryonic theory was received with much enthusiasm, but it has at the present day lost the position which it once held. It may undoubtedly serve to explain some non-malignant growths but it will not avail to explain malignant tumours. A very full account is given of the parasitic theories of cancer, for it occupies nearly 200 pages. All these questions are carefully discussed by the author who holds that the conclusion of the whole matter is that the cause of cancer is still an unsolved riddle. This volume contains certainly the most complete exposition of the study of cancer from the historical point of view with which we are acquainted.

Health at its Best versus Cancer. By ROBERT BELL, M.D. Glasg., F.F.P.S. Glasg., formerly Senior Physician to the Glasgow Hospital for Women. London and Leipsic: T. Fisher Unwin. 1908. Pp. 320. Price 5s. net.—In so far as this book is an appeal for more hygienic living, for more fresh air, for a simpler diet, and for a more natural life, we cannot but agree with it, but when the author maintains that surgery "in no instance can …… possibly hold out the remotest prospect of conferring any benefit whatever" in cases of malignant disease we must dissent entirely.

mentally defective but only the worst, for there are many mentally defective who are considered to be fit for penal discipline. The prison commissioners, to whom all these facts have long been familiar, have already made regulations for dealing with the weak-minded in local prisons but the regulations, good as they are, do not suffice. It has been suggested that on conviction mentally defective persons should be committed to feeble-minded homes or colonies, places of the nature of a half-way house between a prison and a lunatic asylum. In regard to those committed to convict prisons the same evils obtain. At Parkhurst, where there are a considerable number of weak-minded convicts, they are brought together and treated as if they were in a labour-colony. Under this *régime* the convicts behave much better than under the ordinary prison rules and are more easy to manage. From the [illegible] that many competent observers a[illegible] the constantly recurring and fatuous crimes of mentally defective persons are to be prevented long and continuous detention of such persons will be necessary. "From the earliest age when they appear before the magistrate as children on remand or as juvenile offenders, until and throughout the adult period of their lives the mentally defective, at first reprimanded and returned to their parents, then convicted and subjected to a short sentence and returned to their parents, and then later continually sentenced and re-sentenced and returned to their parents or friends till for crimes of greater gravity they pass to the convict prisons, are treated, as this reiterated evidence shows, without hope and without purpose, and in such a way as to allow them to become delinquents of the worst type and to propagate a feeble progeny which may become criminal like themselves." With a view to coping with these problems it is recommended that a central authority should be responsible for the supervision of all cases of mental defect; that local authorities should be responsible for making provision for such cases; that there should be a statutory obligation imposed on the police and all prison authorities to report all these cases to the local authority; and that all courts of justice should have power to order the detention of a mentally defective person in a suitable institution instead of pronouncing a sentence of imprisonment.

That there is a large number of mentally defective persons among those who are to be found in the casual wards, common lodging-houses, and refuges is certain. Many of these are physically and morally dangerous and the Commission has reached the conclusion that there should be some system by which these persons should be brought under an authoritative control by which they could be detained and made to labour according to their ability. So, too, experience has shown that many cases of habitual inebriety are associated with mental defect, and the Commission suggests that the powers of the county committees and of the Board of Control should extend to mentally defective inebriates as well as to other classes of the mentally defective. Other recommendations with reference to this subject are that the county councils should be placed under legal obligation to provide accommodation for mentally defective inebriates and that the Inebriates Act should be amended to facilitate the committal to suitable institutions of persons who are shown to the satisfaction of a criminal court to be mentally defective inebriates.

A large mass of evidence has come before the Commission indicating that, in addition to those who are certified as lunatics, there is another large class of persons who can be with difficulty distinguished from the "certifiably insane" who are socially dangerous and who from weakness of mind are not wholly responsible, and accordingly the question arises whether the condition of being irresponsible should not also attach to other mentally defective persons besides certified lunatics. In the trial of such persons the Commission suggests the adoption of the important principle that the question of the committal of an alleged offence should be separated from the question of alleged mental defect in the accused person and his consequently relative responsibility and from the problem as to his appropriate treatment. On this principle it is proposed that in a court of summary jurisdiction the justices should, prior to conviction, remand the accused to a suitable receiving house, and subsequently, if the medical certificates justified such a course, order the reception of the accused in an institution considered suitable by the committee for the care of the mentally defective. On the same principle, after the conviction of the offender he might be bound over to come up for judgment on the surety of a representative of the committee. The same procedure is suggested for use at assizes and quarter sessions. If any sentence be imposed by the court it is suggested that it should have such reference to the fact of the committal of the offence as the court may decide to be just, but that afterwards, where necessary, a reception order should be made which would be renewable from time to time and which would lead to such treatment and care as from the point of view of mental defect the committee might think necessary.

RECENT EXPERIMENTS ON PLAGUE DISINFECTANTS IN INDIA.

THE following are the main portions of a lengthy scientific report on the use of disinfectants in connexion with plague addressed by Captain W. Glen Liston, I.M.S., Acting Director of the Bombay Bacteriological Laboratory, to the Sanitary Commissioner with the Government of India and now published by the latter. The experiments on the pulicidal powers of the disinfectants enumerated below have been carried out by Captain T. H. Gloster, I.M.S., with much labour and care. It will be well at the outset properly to appraise the value of disinfection in connexion with plague. It is an axiom to state that a disinfectant can only be useful when applied directly to the micro-organisms which it is required to kill. In order, then, that a disinfectant may be usefully employed to combat the spread of plague, it is necessary to know where and to what extent plague germs may exist in nature.

Channels of Plague Infection.

It has recently been conclusively proved that the plague is communicated to man from rats by means of rat fleas. The disease is seldom, if ever, except by accident, transmitted directly from sick persons to healthy individuals; in other words, contact with the excreta of sick animals or man is rarely the means by which the disease is acquired. Excreta, if they contain plague bacilli, are, as a rule, harmless. The plague bacilli when present in excreta rapidly disappear from them; the excreta become disinfected by natural processes, a few hours sufficing in the Indian climate to bring about the destruction of any plague bacilli in them. This natural disinfection is accomplished either by exposure of the plague bacilli to desiccation or in moist conditions is brought about by the development and multiplication of saprophytic bacteria which are inimical to the existence of plague bacilli. Plague is communicated from rats to rats and from rats to man by means of the rat flea. In the body of this insect the plague bacilli are protected from the above-mentioned natural disinfectants. Here they are protected from desiccation and from the action of saprophytic bacteria. In the stomach of the flea, too, they find a suitable food-supply in the blood which is sucked by the insect from its host. The digestive processes going on in the stomach of the flea appear to cause little injury to the plague bacilli. As long as the flea remains alive the bacilli are protected and preserved. On the death of the flea the natural disinfection processes referred to above quickly destroy any plague bacilli which may have been present in its body. We are thus in a position to know that plague bacilli exist in nature either in the body of a plague-sick animal (chiefly the rat) or in the stomach of a rat flea which has fed on such an animal. Any disinfectant to be useful must be directed against the plague bacilli in these situations. The destruction of infected rats and fleas will bring about the destruction of the plague bacilli within their bodies. The bacilli only retain a successful existence in the living bodies of these creatures.

Successful Disinfection.

The most successful disinfectant will be the one which is capable of destroying both rats and their fleas. The fact that rats and fleas are generally to be found in places inaccessible to the application of the ordinary disinfectants materially handicaps the use of these substances; indeed, it may be said that the occasions when the common disinfectants may be used with advantage are few and far

new arsenical compounds, the application of the opsonic index to diagnosis, the use of lactic acid organisms for suppressing the growth of the colon organisms, the ophthalmic method of diagnosing tuberculosis, the modern methods of estimating the germicidal value of disinfectants, and so on. In order to meet the demand thus made on the pages of the new edition a large amount of the matter to which experience shows reference is less frequently made has been reset in small type. Lastly, in spite of the addition of 128 pages more than was contained in the previous edition, the use of a different paper has enabled the authors to produce in the present issue a thinner volume than the last.

JOURNALS AND MAGAZINES.

Annals of Tropical Medicine and Parasitology, University of Liverpool. Vol. II., No. 1, pp. 51; No. 2, pp. 92; No. 3, pp. 122. London: Williams and Norgate. Price 7*s.* 6*d.* net.—In No. 1 Sir Rubert Boyce and Dr. Anton Breinl contribute a communication on Atoxyl and Trypanosomiasis. They begin by giving a sketch of the early observations of the use of arsenic in the treatment of diseases caused by flies. They deal with the employment of the aniline colours in the combined treatment with arsenic and colours and then with atoxyl. The atoxyl treatment is dealt with at very considerable length. With regard to the existence of a second phase in the life cycle of the trypanosome stated so definitely as existing, we should have been more satisfied had reference been made to some of the recent work on blood platelets. The figures illustrating various forms of platelets in normal blood are similar to the figures of some of the stages in the life cycle of trypanosomes by Moore and Breinl, but some evidence appears to be necessary to show that no mistakes exist. Another paper on Trypanosomiasis and its Treatment by Atoxyl and other Drugs is contributed by Sir Patrick Manson. He describes his own personal observations in the treatment of this disease and ascribes great success to the atoxyl treatment. The first contribution to No. 2 is formed by the reports of the "Sleeping Sickness" Expedition to the Zambesi for the years 1907–08, by Dr. Allan Kinghorn and Mr. R. Eustace Montgomery, M.R.C.V.S. The first part forms an introduction to the actual reports themselves. The objects of the expedition from the Liverpool School of Tropical Medicine were to determine to what extent sleeping sickness had invaded British South African territory, to map out the distribution of tsetse flies, and to advise on means for checking the spread of sleeping sickness. Trypanosomiasis in animals as well as in man was dealt with on this expedition. This introduction consists very largely of correspondence between members of the expedition and various officials which deals mainly with the relation between the existence of the tsetse fly and game. The first interim report of the expedition is concerned with the incidence and prophylaxis of human trypanosomiasis in north-eastern Rhodesia. This report includes a discussion of preventive measures. The major measures suggested are: control of native movements; segregation of cases; and removal of villages from dangerous zones. The minor measures are: clearing; education of the natives; personal prophylaxis; and the destruction of tsetse flies, their larvæ and pupæ. The same authors' next report is on Trypanosomiasis of Domestic Stock in North-Western Rhodesia. It shows that trypanosomiasis in cattle and other domestic animals is very prevalent in the northern area of Western Rhodesia and that it is due to trypanosoma dimorphon, trypanosoma vivax, and another morphologically allied to trypanosoma Brucei. It is strongly suggested that these trypanosomes may be transmitted by glossina morsitans, stomoxys calcitrans, and a species of lyperosia. The authors also conclude that the treatment, as detailed in previous reports, shows certain indications of success, and they urge for facilities for a continuation of the work on this disease, which tends to stagnate the proper development of a wealthy mineral and agricultural country. The number also contains a report on the work of the Greek Anti-malaria League during the year 1907, by M. Hadjimichalis, President, and Jean P. Cardamatis, general secretary. It is shown that in 12 principal towns in Greece the average number of deaths from malaria is 287, or 9·8 per 10,000 inhabitants. It is pointed out, however, that these figures do not give any exact idea of the prevalence of malaria throughout the country, as this disease is much less frequent in the towns than in the rural districts. For instance, an examination of the school children held at Marathon in October, 1906, showed that enlargement of the spleen was to be found in every pupil. A detailed account of the work done by the League during the year 1907 is given. The Government has been induced to pass some laws with regard to the sale of quinine which will appear somewhat curious to us in this country. The plain of Marathon was taken in hand particularly by the League, and the reports of the local medical men showed that the number of cases of malaria in this district averages between 80 and 90 per cent. of the population. Considerable work was done in getting rid of the larvæ of mosquitoes. No. 3 of these annals contains the following papers. 1. A Peculiar Intralobular Cirrhosis of the Liver produced by the Protozoal Parasite of Kala-Azar, by Major Leonard Rogers, M.D. Lond., F.R.C.P. Lond., I.M.S. The author in this paper shows that the most chronic cases of kala-azar not infrequently terminate their course with ascites due to cirrhosis of the liver. The cirrhosis is of a peculiar intralobular type of uniform distribution and with a smooth surface to the organ. It is due to the protozoan parasite of kala-azar which may be found in the liver and other organs after death. This form of cirrhosis of the liver is much commoner in Lower Bengal than a "true natural cirrhosis," with which it has probably hitherto been confused. It is, however, much less common than atrophic cirrhosis due to unknown causes. 2. What is "Schistosomum Mansoni" Sambon 1907? by Dr. A. Looss. This contribution is a highly controversial one. The author seeks to show that a species of blood fluke, which was described by Dr. L. W. Sambon in 1907 as being a new species and called by him "Schistosomum Mansoni," is not a new species at all but is schistosomum hæmatobium. The author, Dr. Looss, certainly brings very weighty arguments in favour of his view. It is impossible to deal with this lengthy communication in detail. 3. The Prevention of Dengue Fever, by E. H. Ross, M.R.C.S. Eng., L.R.C.P. Lond., medical officer of health, Port Said. In this very brief communication the author puts forward a plea for the extension of the campaign against mosquitoes in Egypt. 4. The Life History of Trypanosoma Lewisi, by J. E. Salvin-Moore, Anton Breinl, and Edward Hindle. The authors in this communication deal with the life cycle of trypanosoma Lewisi in the same way as they previously dealt with trypanosoma Gambiense and trypanosoma equiperdum. 5. Notes on the Effects of Therapeutic Agents on Trypanosomes in respect to (*a*) Acquired Resistance of the Parasites to the Drug, and (*b*) Changes in Virulence of the Strains after Escape from the Drug, by Benjamin Moore, M.A., D.Sc. R.U.I., Maximilian Nierenstein, Ph.D. Berne, and John Lancelot Todd, B.A., M.D. McGill. The acquirement of resistance to various toxins and parasites by man and other animals has been much studied. In th present communication a less known, but allied, subject is dealt with. This is the acquirements of resistance to poisons mentally defective but only the worst, for there are many mentally defective who are considered to be fit for penal discipline. The prison commissioners, to whom all these facts have long been familiar, have already made regulations for dealing with the weak-minded in local prisons but the regulations, good as they are, do not suffice. It has been suggested that on conviction mentally defective persons should be committed to feeble-minded homes or colonies, places of the nature of a half-way house between a prison and a lunatic asylum. In regard to those committed to convict prisons the same evils obtain. At Parkhurst, where there are a considerable number of weak-minded convicts, they are brought together and treated as if they were in a labour-colony. Under this *régime* the convicts behave much better than under the ordinary prison rules and are more easy to manage. From the evidence it appears that many competent [illegible] if the constantly recurring [illegible] mentally defective persons are to be prevented long and continuous detention of such persons will be necessary. "From the earliest age when they appear before the magistrate as children on remand or as juvenile offenders, until and throughout the adult period of their lives the mentally defective, at first reprimanded and returned to their parents, then convicted and subjected to a short [illegible] returned to their parents, and then lat[illegible] sentenced and re-sentenced and returned to their parents or friends till for crimes of greater gravity they pass to the convict prisons, are treated, as this reiterated evidence shows, without hope and without purpose, and in such a way as to allow them to become delinquents of the worst type and to propagate a feeble progeny which may become criminal like themselves." With a view to coping with these problems it is recommended that a central authority should be responsible for the supervision of all cases of mental defect; that local authorities should be responsible for making provision for such cases; that there should be a statutory obligation imposed on the police and all prison authorities to report all these cases to the local authority; and that all courts of justice should have power to order the detention of a mentally defective person in a suitable institution instead of pronouncing a sentence of imprisonment.

That there is a large number of mentally defective persons among those who are to be found in the casual wards, common lodging-houses, and refuges is certain. Many of these are physically and morally dangerous and the Commission has reached the conclusion that there should be some system by which these persons should be brought under an authoritative control by which they could be detained and made to labour according to their ability. So, too, experience has shown that many cases of habitual inebriety are associated with mental defect, and the Commission suggests that the powers of the county committees and of the Board of Control should extend to mentally defective inebriates as well as to other classes of the mentally defective. Other recommendations with reference to this subject are that the county councils should be placed under legal obligation to provide accommodation for mentally defective inebriates and that the Inebriates Act should be amended to facilitate the committal to suitable institutions of persons who are shown to the satisfaction of a criminal court to be mentally defective inebriates.

A large mass of evidence has come before the Commission indicating that, in addition to those who are certified as lunatics, there is another large class of persons who can be with difficulty distinguished from the "certifiably insane" who are socially dangerous and who from weakness of mind are not wholly responsible, and accordingly the question arises whether the condition of being irresponsible should not also attach to other mentally defective persons besides certified lunatics. In the trial of such persons the Commission suggests the adoption of the important principle that the question of the committal of an alleged offence should be separated from the question of alleged mental defect in the accused person and his consequently relative responsibility and from the problem as to his appropriate treatment. On this principle it is proposed that in a court of summary jurisdiction the justices should, prior to conviction, remand the accused to a suitable receiving house, and subsequently, if the medical certificates justified such a course, order the reception of the accused in an institution considered suitable by the committee for the care of the mentally defective. On the same principle, after the conviction of the offender he might be bound over to come up for judgment on the surety of a representative of the committee. The same procedure is suggested for use at assizes and quarter sessions. If any sentence be imposed by the court it is suggested that it should have such reference to the fact of the committal of the offence as the court may decide to be just, but that afterwards, where necessary, a reception order should be made which would be renewable from time to time and which would lead to such treatment and care as from the point of view of mental defect the committee might think necessary.

RECENT EXPERIMENTS ON PLAGUE DISINFECTANTS IN INDIA.

The following are the main portions of a lengthy scientific report on the use of disinfectants in connexion with plague addressed by Captain W. Glen Liston, I.M.S., Acting Director of the Bombay Bacteriological Laboratory, to the Sanitary Commissioner with the Government of India and now published by the latter. The experiments on the pulicidal powers of the disinfectants enumerated below have been carried out by Captain T. H. Gloster, I.M.S., with much labour and care. It will be well at the outset properly to appraise the value of disinfection in connexion with plague. It is an axiom to state that a disinfectant can only be useful when applied directly to the micro-organisms which it is required to kill. In order, then, that a disinfectant may be usefully employed to combat the spread of plague, it is necessary to know where and to what extent plague germs may exist in nature.

Channels of Plague Infection.

It has recently been conclusively proved that the plague is communicated to man from rats by means of rat fleas. The disease is seldom, if ever, except by accident, transmitted directly from sick persons to healthy individuals; in other words, contact with the excreta of sick animals or man is rarely the means by which the disease is acquired. Excreta, if they contain plague bacilli, are, as a rule, harmless. The plague bacilli when present in excreta rapidly disappear from them; the excreta become disinfected by natural processes, a few hours sufficing in the Indian climate to bring about the destruction of any plague bacilli in them. This natural disinfection is accomplished either by exposure of the plague bacilli to desiccation or in moist conditions is brought about by the development and multiplication of saprophytic bacteria which are inimical to the existence of plague bacilli. Plague is communicated from rats to rats and from rats to man by means of the rat flea. In the body of this insect the plague bacilli are protected from the above-mentioned natural disinfectants. Here they are protected from desiccation and from the action of saprophytic bacteria. In the stomach of the flea, too, they find a suitable food-supply in the blood which is sucked by the insect from its host. The digestive processes going on in the stomach of the flea appear to cause little injury to the plague bacilli. As long as the flea remains alive the bacilli are protected and preserved. On the death of the flea the natural disinfection processes referred to above quickly destroy any plague bacilli which may have been present in its body. We are thus in a position to know that plague bacilli exist in nature either in the body of a plague-sick animal (chiefly the rat) or in the stomach of a rat flea which has fed on such an animal. Any disinfectant to be useful must be directed against the plague bacilli in these situations. The destruction of infected rats and fleas will bring about the destruction of the plague bacilli within their bodies. The bacilli only retain a successful existence in the living bodies of these creatures.

Successful Disinfection.

The most successful disinfectant will be the one which is capable of destroying both rats and their fleas. The fact that rats and fleas are generally to be found in places inaccessible to the application of the ordinary disinfectants materially handicaps the use of these substances; indeed, it may be said that the occasions when the common disinfectants may be used with advantage are few and far

aptly terms "the bane of Irish mortality statistics," has been specially discussed in several of his recent reports. From an instructive diagram showing the relative mortality from the principal causes in Ireland we note that the column representing tuberculosis stands highest in the list. The deaths from all forms of this disease amounted to 15 per cent. of the mortality from all causes and to a rate of 2·7 per 1000 of the population. From another diagram it appears that since the year 1864 the rate of mortality from tuberculous diseases in Ireland has *increased* from 2·4 to 2·7 per 1000, whereas in England it has *decreased* in the same interval from 3·3 to 1·6 per 1000. From yet another diagram we learn that whilst in Ireland the age of highest mortality from tuberculosis is from the twenty-fifth to the thirty-fifth year, when it is fatal to 4·5 per 1000 of the population living at that age, in England, on the other hand, the age of the highest mortality is ten years later—viz., from the thirty-fifth to the forty-fifth year, when it is fatal to only 2·0 per 1000 of the population.

In Ireland, as elsewhere, tuberculous phthisis is by far the most fatal member of the tuberculous group. The deaths there attributed to this disease in 1907 accounted for a mortality at the rate of 2·02 per 1000, as compared with 1·15 in England and Wales. The sex incidence of tuberculous phthisis in the two divisions of the kingdom differs materially, for whilst in England the disease is considerably more destructive at all ages to males than to females in Ireland the sexes succumb to it in practically equal proportions. When, however, account is taken of the ages of those who die we find that from the fifteenth to the twentieth year women die faster than men from this disease, whilst at most subsequent ages the reverse holds good. We have before mentioned that the reports of the Registrar-General for Ireland have an advantage over the reports of the Registrars-General of England and Scotland in that the former alone show the variations of mortality among the several social grades of the community. The report before us contains a chart showing the behaviour of tuberculous phthisis in four "general classes" of the Irish people in the course of the last seven years. In the "general service class" the mortality is highest, 2·4 per 1000; the "artisan class" comes next with a rate of 2·1 per 1000; whilst the mortality of the "professional and independent class" is the lowest and does not exceed 0·8 per 1000. The "middle class" is the only one of the four which has shown no decrease in phthisical mortality during the last seven years.

At a later stage in the report the Registrar-General has some interesting remarks on the connexion of tuberculous phthisis with bronchitis, as well as with pleurisy and empyema. "In a certain sense," he observes, "bronchitis may, from a public health point of view, be considered as a preventable disease, and the reduction of its death-rate may be regarded as one of the indices of improvement in the social conditions under which our people are living." From a comparison of the death-rates from bronchitis in England and Ireland it appears that the mortality from that disease in the latter country exceeds that in the former by 43 per 100,000 living. The disparity is still more strongly marked if the death-rate from tuberculous disease be taken into account, for in that case there is a difference against Ireland of 142 per 100,000. In other words, if the death-rates from tuberculous disease and from bronchitis had been only the same as in England, the mean mortality from all causes together in Ireland in the decennium 1897–1906 would have stood at 16·48 per 1000, instead of at 17·90 per 1000 as it appears in the tables. Adverting to the instruction contained in the official nomenclature of the Royal College of Physicians of London to the effect that "when pleurisy is known to be tuberculous the fact should be stated," Sir Robert Matheson reports that in the year under notice 34 deaths were certified to be due to empyema without mention of probable cause. In each of these cases a query for further information was issued from his office, with the result that more than one-third of them were found to have a tuberculous origin. In the course of the last decennium inquiry was made respecting 121 deaths from empyema, the result being that as many as 53 of the patients were believed to be suffering from tuberculosis in one or another of its varieties.

With respect to the behaviour of cancer or malignant disease in Ireland, the Registrar-General's statistics are commendably complete. In the course of the ten years ending with 1900 the rate of cancer mortality increased from 46·2 per 100,000 living to 60·8. In the year 1901 it further increased to 65·1, and to 79·3 in 1906. In the year under present review, however, it fell slightly, being equal to 76·2 per 100,000 of the population. In the case of tumours stated in the medical certificates to be the cause of death, the system of inquiry from the medical certifier is adopted as in England, and as a result the death from tumour is in a large number of instances removed from that indefinite heading and referred to malignant disease. Even in the year 1907 alone not less than 75 deaths were removed from causes of a more or less doubtful nature and classed in one or another of the diseases of malignant nature. In order to ascertain the relative sex incidence of malignant disease it has been the custom to exclude the deaths of persons under the age of 35 years and to calculate the death-rates in the male and female population estimated to be living at ages above 35 years. Computed in this way the cancer death-rate was 2·02 per 1000 for men and 2·22 per 1000 for women. In the previous year the male rate in Ireland had been 2·07 per 1000 and the female rate 2·36 per 1000, the English rates for that year being 2 and 3·04 per 1000 respectively. From the above figures it would appear as though malignant disease were more disastrous to the female than to the male sex. From a table it appears that of 3338 deaths in all 1530 were those of men and 1808 those of women; but of the latter total 262 deaths were caused by cancer of the uterus and 287 by cancer of the female breast (against seven only from cancer of the male breast). If from the total female deaths the 549 deaths last mentioned be omitted, it will be seen that the male sex is considerably more liable to fatal cancer than is the female. In both sexes the organ most frequently affected by malignant disease is the stomach, 434 males and 396 females having died from affections of this organ in the year under notice. Excluding affections of the mammary and generative systems, the liver and gall-bladder are the organs coming next in frequency of attack, but of the deaths thus caused the majority occurred among women.

The Registrar-General reports with regret that in the year under notice not less than 14,299, or 18 per cent., of the deaths registered were referred to causes so imperfectly defined as to be useless for statistical purposes. The deaths under this heading comprise those referred to atrophy, old age, dropsy, tumours, abscess, hæmorrhage, sudden death, and other ill-defined or unspecified causes. In this connexion the Registrar-General makes the following appeal: "I may mention that I am now issuing suggestions to each member of the medical profession in Ireland, whose name appears in the Register, regarding certificates of causes of death, and I most earnestly ask for help from one and all, to enable me to produce the mortality statistics of Ireland in as perfect a condition as possible." Of the total deaths registered in Ireland last year not less than one-fourth part were uncertified, as compared with 2·3 per cent. for Scotland and 1·5 per cent. for England. Sir Robert Matheson attributes this large proportion of uncertified deaths to the custom which prevails in some of the rural parts of Ireland of not seeking medical advice, especially for the aged. The very large area of most of the dispensary districts also involves special geographical difficulties in procuring timely medical help in the hour of sickness. In these circumstances the Registrar-General has found it necessary from time to time to issue circulars to all medical registrars impressing upon them the importance of certifying causes of death in the case of their own patients. The Irish Local Government Board has also been requested to exercise its influence in this matter on the dispensary medical officers who act under its direction. Although the proportion of uncertified deaths is still very high it is satisfactory to note that it is steadily though slowly falling.

We heartily congratulate Sir Robert Matheson on the general excellence of the forty-fourth annual report and for the promptness with which it has been issued; and we are sure that the medical profession in Ireland will appreciate the graceful terms in which the Registrar-General acknowledges the services of Dr. Ninian McIntire Falkiner in its production.

HOSPITAL SATURDAY AT NEWTON ABBOT (DEVON).—£274 were collected recently in Newton Abbot for the Hospital Saturday fund. This is £54 in excess of any previous Hospital Saturday collection.

mentally defective but only the worst, for there are many mentally defective who are considered to be fit for penal discipline. The prison commissioners, to whom all these facts have long been familiar, have already made regulations for dealing with the weak-minded in local prisons but the regulations, good as they are, do not suffice. It has been suggested that on conviction mentally defective persons should be committed to feeble-minded homes or colonies, places of the nature of a half-way house between a prison and a lunatic asylum. In regard to those committed to convict prisons the same evils obtain. At Parkhurst, where there are a considerable number of weak-minded convicts, they are brought together and treated as if they were in a labour colony. Under this *régime* the convicts behave much better than under the ordinary prison rules and are more easy to manage. From the evidence it appears that many competent observers are of opinion that if the constantly recurring and fatuous crimes of mentally defective persons are to be prevented long and continuous detention of such persons will be necessary. "From the earliest age when they appear before the magistrate as children on remand or as juvenile offenders until and throughout the adult period of their lives the mentally defective, at first reprimanded and returned to their parents, then convicted and subjected to a short sentence and returned to their parents, and then later continually sentenced and re-sentenced and returned to their parents or friends till for crimes of greater gravity they pass to the convict prisons, are treated, as this reiterated evidence shows, without hope and without purpose, and in such a way as to allow them to become delinquents of the worst type and to propagate a feeble progeny which may become criminal like themselves." With a view to coping with these problems it is recommended that a central authority should be responsible for the supervision of all cases of mental defect; that local authorities should be responsible for making provision for such cases; that there should be a statutory obligation imposed on the police and all prison authorities to report all these cases to the local authority; and that all courts of justice should have power to order the detention of a mentally defective person in a suitable institution instead of pronouncing a sentence of imprisonment.

That there is a large number of mentally defective persons among those who are to be found in the casual wards, common lodging-houses, and refuges is certain. Many of these are physically and morally dangerous and the Commission has reached the conclusion that there should be some system by which these persons should be brought under an authoritative control by which they could be detained and made to labour according to their ability. So, too, experience has shown that many cases of habitual inebriety are associated with mental defect, and the Commission suggests that the powers of the county committees and of the Board of Control should extend to mentally defective inebriates as well as to other classes of the mentally defective. Other recommendations with reference to this subject are that the county councils should be placed under legal obligation to provide accommodation for mentally defective inebriates and that the Inebriates Act should be amended to facilitate the committal to suitable institutions of persons who are shown to the satisfaction of a criminal court to be mentally defective inebriates.

A large mass of evidence has come before the Commission indicating that, in addition to those who are certified as lunatics, there is another large class of persons who can be with difficulty distinguished from the "certifiably insane" who are socially dangerous and who from weakness of mind are not wholly responsible, and accordingly the question arises whether the condition of being irresponsible should not also attach to other mentally defective persons besides certified lunatics. In the trial of such persons the Commission suggests the adoption of the important principle that the question of the committal of an alleged offence should be separated from the question of alleged mental defect in the accused person and his consequently relative responsibility and from the problem as to his appropriate treatment. On this principle it is proposed that in a court of summary jurisdiction the justices should, prior to conviction, remand the accused to a suitable receiving house, and subsequently, if the medical certificates justified such a course, order the reception of the accused in an institution considered suitable by the committee for the care of the mentally defective. On the same principle, after the conviction of the offender he might be bound over to come up for judgment on the surety of a representative of the committee. The same procedure is suggested for use at assizes and quarter sessions. If any sentence be imposed by the court it is suggested that it should have such reference to the fact of the committal of the offence as the court may decide to be just, but that afterwards, where necessary, a reception order should be made which would be renewable from time to time and which would lead to such treatment and care as from the point of view of mental defect the committee might think necessary.

RECENT EXPERIMENTS ON PLAGUE DISINFECTANTS IN INDIA.

THE following are the main portions of a lengthy scientific report on the use of disinfectants in connexion with plague addressed by Captain W. Glen Liston, I.M.S., Acting Director of the Bombay Bacteriological Laboratory, to the Sanitary Commissioner with the Government of India and now published by the latter. The experiments on the pulicidal powers of the disinfectants enumerated below have been carried out by Captain T. H. Gloster, I.M.S., with much labour and care. It will be well at the outset properly to appraise the value of disinfection in connexion with plague. It is an axiom to state that a disinfectant can only be useful when applied directly to the micro-organisms which it is required to kill. In order, then, that a disinfectant may be usefully employed to combat the spread of plague, it is necessary to know where and to what extent plague germs may exist in nature.

Channels of Plague Infection.

It has recently been conclusively proved that the plague is communicated to man from rats by means of rat fleas. The disease is seldom, if ever, except by accident, transmitted directly from sick persons to healthy individuals; in other words, contact with the excreta of sick animals or man is rarely the means by which the disease is acquired. Excreta, if they contain plague bacilli, are, as a rule, harmless. The plague bacilli when present in excreta rapidly disappear from them; the excreta become disinfected by natural processes, a few hours sufficing in the Indian climate to bring about the destruction of any plague bacilli in them. This natural disinfection is accomplished either by exposure of the plague bacilli to desiccation or in moist conditions is brought about by the development and multiplication of saprophytic bacteria which are inimical to the existence of plague bacilli. Plague is communicated from rats to rats and from rats to man by means of the rat flea. In the body of this insect the plague bacilli are protected from the above-mentioned natural disinfectants. Here they are protected from desiccation and from the action of saprophytic bacteria. In the stomach of the flea, too, they find a suitable food-supply in the blood which is sucked by the insect from its host. The digestive processes going on in the stomach of the flea appear to cause little injury to the plague bacilli. As long as the flea remains alive the bacilli are protected and preserved. On the death of the flea the natural disinfection processes referred to above quickly destroy any plague bacilli which may have been present in its body. We are thus in a position to know that plague bacilli exist in nature either in the body of a plague-sick animal (chiefly the rat) or in the stomach of a rat flea which has fed on such an animal. Any disinfectant to be useful must be directed against the plague bacilli in these situations. The destruction of infected rats and fleas will bring about the destruction of the plague bacilli within their bodies. The bacilli only retain a successful existence in the living bodies of these creatures.

Successful Disinfection.

The most successful disinfectant will be the one which is capable of destroying both rats and their fleas. The fact that rats and fleas are generally to be found in places inaccessible to the application of the ordinary disinfectants materially handicaps the use of these substances; indeed, it may be said that the occasions when the common disinfectants may be used with advantage are few and far

medicine licence should be raised very considerably, a proposition which we heartily endorse. He further proposed that a board of control, consisting largely of recognised authorities in the different branches of medicine, should be constituted, to which it should be made compulsory for the composition of every secret remedy to be submitted for registration before permission could be given for its public advertisement or the imprimatur of the Government stamp. This proposal, however, would have to be considered carefully, for we doubt both its advisability and practicability. We have from time to time published analyses of many of the quack medicines which are on the market and have demonstrated how useless they are, but a certain section of the public appears to enjoy being victimised and nothing short of stringent legislation will diminish the profits of the patent medicine vendor. Mr. Wright's remarks on the various matters connected with pharmacy are well worth careful consideration; the pharmacists working loyally with the members of the medical profession, as he urged them to do, can perform inestimable service to the public. There are much room and need for pharmaceutical research but this can only be successfully accomplished if those engaged in that undertaking are willing to give themselves unselfishly to the work and to [illegible]r diligently for the good of the community.

◆

The Sanitary Defence of the Hedjaz Railway.

THE present situation in the East, whether Near East, Middle East, or Far East, is one of absorbing interest. No publicist, be his sphere of activity never so specialised, can stand by unconcerned, unmoved by the spectacle of the dramatic series of events that have unrolled themselves in the last few years in one Oriental country after another. The volcanic upheaval of Japan as a first-class "European" power, the domestic troubles in the vast Russian empire, the "unrest" in India and in Egypt, the reign of anarchy in Persia—these events have succeeded each other with almost breathless rapidity. And now, most recent in this closely linked chain, has come the peaceful revolution in Turkey, where, after 30 years of Palace rule, the people have forced their ruler to grant them liberty and a constitution, have put to ignominious flight the Palace clique, and are now rejoicing in their newly acquired freedom. No one can withhold his meed of admiration at the manner in which this tremendous change has been brought about by the Turkish people themselves and at the wonderful restraint and self-control which they have shown in circumstances such as, in other countries in the past, have too often led to anarchy and bloodshed. That the occurrences briefly enumerated above, which have marked the recent history of so many eastern countries, are closely inter-connected, each with the others, it is impossible not to believe; and they afford abundant material for the philosopher anxious to find in them some guiding and connecting principle, and endeavouring to draw from them conclusions that may help to raise, be it by ever so little, the veil that hides the near future. Is the East really waking from its age-long sleep? Are we on the eve of great secular events, where East and West shall at last "meet"? Shall that meeting take the form of a friendly rivalry and a treading side by side the paths marked out by "western" civilisation, or will it end in the shock of arms and the ghastly carnage of a modern Armageddon? Or, finally, will another and a different form of civilisation be ultimately evolved, face to face with which that particular form of it which we call "western" may find it hard to hold its own and may have to yield and to modify itself beyond recognition?

Almost simultaneously with the granting of the constitution in Turkey the railway which unites Damascus with Medina has been completed and formally opened. This alone would at any other time have appealed irresistibly to the imagination and have justified speculations almost as far-reaching as those in which we have just ventured to indulge. Coming as it does at this particular moment it acquires an added significance and appeals with increased force to the imagination of all thinking people. In this brief column, however, we cannot follow further the fascinating lines of speculative thought which such an event as this inevitably opens up. The completion of the Hedjaz railway may, indeed, be considered from so many different aspects that it could well furnish themes for innumerable articles, but we must content ourselves here with considering it from one aspect only—the influence which the line must inevitably have on the spread of disease and the means by which this new danger will have to be met. We publish to-day the first of a short series of articles on this subject which has been sent to us by the British Delegate on the Constantinople Board of Health. The writer has recently returned from a journey down the Hedjaz Railway as far as Medaini-Salih, only some 180 miles north of Medina. As perhaps the first English medical man who has ever visited those regions (to which, indeed, few Europeans of any kind have hitherto penetrated) his articles offer a special interest. The journey was accomplished as member of a Commission sent by the Constantinople Board of Health, with the general mandate to study on the spot the sanitary defence of the line, and the special mandate to select the best site for a lazaret, in which pilgrims returning from Mecca and Medina will undergo disinfection, and if necessary quarantine, before reaching Damascus. The results of the Commission's labours are set forth at length in the articles in question. Tebuk, a place about half-way between Damascus and Medina, but rather nearer the latter, has been chosen as the site for the quarantine station; and a series of definite proposals hav been made by the Commission for the sanitary defence of the line, the execution of which is now seriously occupying the international sanitary board above referred to. The question of "ways and means" is also, we gather, being considere in the proper quarters and will sooner or later form the subject of a new agreement between the Porte and the Powers interested.

To the measures proposed by the Commission in question we may perhaps refer again and in more detail in a later issue. We would only say now that a thorough scheme of defence of this new channel of communication is of first-rate importance in the interests of the public health of all

Public Health Acts being inserted in the local Act legalising the measure. Since the beginning of voluntary notification 872 cases have been notified and during the whole of this period, 1902–07, there have been multiple cases in 25 houses only. The corporation has now secured four additional beds at Meathop sanatorium in Westmorland, this making eight beds in all. Of the total 15 cases discharged from the sanatorium between July, 1906, and the end of 1907, three are regarded as "cured," four as fit for light work, three as improved in general health but unfit for light work, and five show no improvement.

County Borough of Warrington.—Dr. J. C. Hibbert, the successor to the la [illegible] alth, treads cautiously in his first [illegible] no hesitation in condemning the [illegible] at present obtains and in advoc [illegible] tem. As he observes, it is a [illegible] majority of houses [illegible] hard by their back-doors and polluting the air of the [illegible] larders. It is remarkable that in the north [illegible] the people suffer these accumulations of [illegible] refuse in much more docile fashion than would be the case in the south, although there is [illegible] change for the better is steadily passing northwards. In discussing the subject of tuberculosis Dr. Hibbert fully recognises the impossibility of isolating notified cases of pulmonary tuberculosis, but he thinks, nevertheless, that much may be done educationally without interfering with the liberty of the sufferers. He proposes that the small-pox hospital when not needed for small-pox should be used for an educational course of instruction and also for accommodating such advanced cases as cannot be properly cared for in their own homes. He thinks, too, that the isolation hospital for ordinary infectious diseases might in part be utilised for educational purposes. There is no doubt that if the patients did not contract other diseases there would be advantage to them in this temporary sojourn. There would be some improvement in their condition and by being taught how to conduct their lives they might live longer than would otherwise be the case. As regards the spread of the disease through tuberculous milk Dr. Hibbert deplores the slowness of the machinery at present available for stopping the supply of tuberculous milk, even with the help of the powers bestowed by the Liverpool milk clauses, owing largely to the long interval necessary to demonstrate the presence or absence of the tubercle bacillus. The Warrington town council seems, however, to have acted wisely in stopping the supply of milk on suspicion and compensating the farmer for the loss. But, as Dr. Hibbert observes, a tuberculous cow turned out of one cowshed may find its way into another and thus continue its supply of tuberculous milk. What is wanted is uniform systematic action all over the country and the same type of action is necessary with regard to the meat-supply. An abattoir is built in a town and all the animals slaughtered there are perhaps duly inspected, as well as the meat of such animals after slaughter. But in the meantime the meat of animals slaughtered elsewhere is introduced under very imperfect supervision.

The Borough of Wimbledon.—Mr. Evelyn Pocklington reports that during the year 1907 15 patients were found to be peeling from scarlet fever at the time when the medical attendant was called in, and he concludes that unrecognised cases of this disease are among the most potent causes of the spread of scarlet fever. Mr. Pocklington thinks that the Metropolitan Asylums Board is quite right in pressing for an inquiry as to the causes of scarlet fever and as to whether any further means can be taken to control the malady. He interprets the attitude of the Asylums Board as indicating that in its opinion notification and isolation have not had the desired effect of keeping the disease in control. During the year under review the medical officer presented a report to the local sanitary authority relative to the question of establishing a municipal milk depôt, but the council, after considering the report, decided that the establishment of such a depôt was not desirable at the present time. Apparently it is more in favour of promoting a pure untreated milk-supply.

County Borough of Ipswich.—Dr. A. M. N. Pringle gives population of this East Anglian town at nearly 73,000, he increase during the last intercensal period has been p in no inconsiderable degree by immigrants. He also sets out the death-rate figures since 1840 and these show, approximately speaking, a fall from 23 to 15 per 1000. During 1907 14·6 per cent. of all the deaths registered in the borough occurred in institutions, there having been, as in many other places, an increasing use made of public institutions during recent years. In Ipswich during the quinquennium ending 1898 only 9·6 per cent. of the total deaths took place in institutions. Dr. Pringle furnishes a good illustration of the manner in which scarlet fever spreads and, incidentally, of the reason why isolation hospitals, dealing as they do with recognised cases alone, have produced less effect in promoting the control of scarlet fever than was anticipated by their founders. A child was treated for a mild attack of sore-throat and three weeks afterwards the child returned to school, where it remained 10 days, after which the mother noticed that the child's hands were peeling. While the child was at home, and presumably before it commenced to peel, it played with several companions in the street and at home, and four of them developed scarlet fever. Two of these cases were at once recognised, but the remaining two were not diagnosed until three and five weeks respectively after attack, and each of these cases infected another member of the family. Here then was an unrecognised case responsible for at least six other cases. Two of the nurses at the isolation hospital contracted enteric fever and in nine cases the medical officer of health attributed infection to the consumption of cockles taken from the river Orwell, all the cases occurring at about the same time—i.e., from the middle of June to the end of the first week in July. The best attested group of cases is the following. Five persons out of a family of six partook of cockles and one was attacked with diarrhœa and vomiting on the next day, complete recovery rapidly ensuing. That member of the family who did not eat cockles—a child, aged six years—remained well. Some three weeks afterwards two of the family were removed to hospital with enteric fever and both yielded Widal's reaction. Two other members of the family also yielded typical Widal's reaction and they, too, were removed; the remaining two members, the child who ate no cockles and the member who had vomiting and diarrhœa, had their blood examined with negative results. At the same time two other cases from another town were taken to hospital with enteric fever and both had eaten cockles. No cases during the remainder of the year could be traced to cockles. The series is an interesting one and we agree that in all probability the cockles were the cause of the disease. As a result of the outbreak posters were exhibited in the district and we believe that similar precautions were taken after an outbreak described by the late medical officer of health which was also ascribed to shellfish taken from the Orwell. Dr. Pringle is hopeful as regards the future of tuberculosis. The disease has, he points out, fallen 50 per cent. during the last 50 years without any special efforts, and he thinks that it is well within the realms of possibility that the disease will share the same fate that has overtaken such diseases as typhus fever and relapsing fever and will practically disappear. He regards the infectivity of the disease as low and not to be ranked with scarlet fever and diphtheria. The public have, in his opinion, arrived at a totally erroneous conception of the degree of infectivity with the result that the ignorant are likely to convert the patient into a social pariah. If progress against the disease is to be maintained the sanitary authority of Ipswich must, he says, wage increasing warfare against the whole of the conditions summed up in the expression "insanitary property."

The Municipality of Shanghai.—The frontispiece of Dr. A. Stanley's annual report is the reproduction of a photograph of the interior of the municipal laboratory, an institution which is doing admirable work in Shanghai. We have already noticed certain aspects of this report but we desire now to draw attention to other points of interest. Some of the figures as regards disease are instructive. For example, small-pox during 1907 claimed 21 deaths among the foreign population and 863 amongst the Chinese. Dr. Stanley states that the Chinese are beginning to appreciate the benefits of vaccination as opposed to inoculation, which they have practised, he adds, with little benefit for hundreds of years. Apparently inoculation is still not illegal in Shanghai and it would be of interest to students of the vaccination question if Dr. Stanley would tell us something as to hypothesis as to the nature of menstruation. They base their conclusions on the study of a specimen which came under their own notice, and on the descriptions of a series of young ova recorded in the literature, the ages of which they have determined from the age and degree of development of the early ovum described by themselves as to which very accurate data are forthcoming. They consider that the menstrual decidua is not in the old sense of the words a preparation for the reception of an ovum, that it does not represent an abortion of an unfertilised ovum, and that menstruation does not necessarily coincide with ovulation. They regard it as a cyclical process which provides for the maintenance of the endometrium in a suitable condition for the production of the decidua of pregnancy. The observations of GRAF VON SPEE and others on the mouse and guinea-pig have demonstrated that the endometrium does not show the slightest trace of alteration from the non-pregnant state until its epithelium has disappeared and the ovum has begun to attack the deeper tissues in the process of imbedding itself, when decidual development rapidly follows. The imbedding of the ovum and the development of the decidua may be concluded in all probability to take place in the same manner in the human subject, and the uterine mucous membrane may be considered as capable of producing a decidua of conservation whenever its integrity is threatened by the young ovum. The observations of TEACHER and BRYCE tend to show that the imbedding of the ovum can take place at any time during the month, even during the quiescent period of the endometrium, and their view therefore that by the recurrence of the menstrual cycle the uterine mucous membrane is maintained in a condition of immaturity most favourable for the development of a decidua seems eminently rational; it is certainly borne out by the arguments which they put forward. At the same time they believe that the most favourable circumstances for successful impregnation are the occurrence of ovulation about the period of menstruation and of insemination shortly before or after the period of discharge.

Annotations.

"Ne quid nimis."

THE MOTOR PROBLEM: A TIMELY CIRCULAR.

THE Local Government Board has recently issued an important circular to county councils and town councils of boroughs dealing with the regulation of motor traffic, in which the grave nuisances and abuses which have resulted from its development are fairly faced. The object of the circular is to remind local authorities of the powers which they already possess to deal with reckless driving under Sections 1, 8, 9, and 11 of the Motor-car Act of 1903. The first of these is the most important, for it provides that—

> If any person drives a motor-car on a public highway recklessly or negligently or at a speed or in a manner which is dangerous to the public, having regard to all the circumstances of the case, including the nature, condition, and use [illegible] amount of traffic which actually is at the [illegible] expected to be on the highway, [illegible] sonably be under the Act. Offences under this section are by Section 11 punishable on summary conviction by a fine not exceeding £20, *or in the case of a second or subsequent conviction* by a fine not exceeding £50, or in the discretion of the court to imprisonment for a period not exceeding three months.
>
> Any police constable may apprehend, without warrant, the driver of any car who commits an offence under Section 1 within his view, if he refuses to give his name and address or produce his licence on demand, or if the motor-car does not bear the marks of identification.

The circular points out that this clause, which bases the consideration of each case upon its own special circumstances, should afford a check upon reckless driving sufficient to obviate the necessity of further legislation in the direction of a drastic speed limit, the disadvantages of which are fully recognised. With regard to the present regulation limiting motor-cars on any public highway to a speed of 20 miles an hour and in certain localities, the authorities of which have made a special application to the Local Government Board, to a speed of 10 miles an hour, it is clearly stated that even where the lower speed limit is not imposed there are innumerable places where the speed should be much less than 20 miles an hour. The Board is anxious that local authorities should enforce this principle rather by applying their powers under the section which we have quoted than by extending the operation of the 10-mile limit, but it acknowledges itself ready to give prompt consideration to applications for powers to make such a local order where circumstances justify it. The circular very rightly strongly discountenances anything in the nature of racing on public roads by motor vehicles. It further observes that "whilst motorists should be required to obey the law it is of importance that the road authorities should use every effort to diminish the risk of accidents from a form of traffic the existence of which cannot be ignored." It suggests the widening of streets, the rounding of corners, the avoiding of central road-posts for tramways, the pruning of hedges near crossways, and the erection of danger signals by local authorities whenever a fair opportunity presents itself, and that the prevention of dust by watering and other treatment, "to mitigate what is undoubtedly a serious cause of complaint," should be systematically undertaken. The gist of the document may be summed up by saying that the Board considers that the steady and systematic enforcement of present powers would largely prevent the wanton abuse of the highway by inconsiderate and reckless drivers. We believe that certain societies interested in the welfare of motorists are using their endeavours to purge their ranks of that class which has brought discredit and even execration upon a vehicle which must inevitably become the chief form of road conveyance of the future. Motor-cars can be, and often are, driven with consideration and even with courtesy, but the remembrance of six well-mannered drivers is swept out of the mind of a pedestrian furious at the insults of a "road-hog" who has charged down upon him in the furious exercise of all the abominable customs of his tribe. Such persons must be repressed in the interests both of the public and of decent drivers, and we trust that local authorities will be stimulated by this timely circular to use the full powers to that end with which they are invested. The dust question presents a harder problem. Of its urgency none can doubt who use any country road upon a rainless day. It does not seem that any material help to its solution has come from various suction devices affixed to the cars. If the Local Government Board is unable to make grants for the treatment of roads it seems that the local authorities must see to it at their own expense, in the interest both of the health and temper of their residents and visitors.

"THE HOSPITAL ASSISTANT."

THE above is the title of a periodical published at Kolhapur (India) and devoted to the interests of that numerous, intelligent, and deserving body of men in the employment of the Government of India who are known officially as hospital assistants. Hitherto the *Hospital Assistant*, to which we have already directed attention,[1] has been issued monthly but, being literally "a one-man journal," when its editor unfortunately fell sick there fell to 35 in the week under notice; of these, 27 occurred in Glasgow and two both in Aberdeen and in Paisley. The 10 fatal cases of whooping-cough, of which nine were recorded in Glasgow, showed a marked decline from recent weekly numbers. The deaths referred to "fever," however, which had been but four and five in the two previous weeks, further rose last week to nine, including five fatal cases of cerebro-spinal fever, three of enteric fever, and one of typhus fever; five of the nine fatal cases of "fever" occurred in Glasgow and one each in Edinburgh, Dundee, Paisley, and Greenock. The seven deaths from diphtheria exceeded recent weekly numbers, and included six in Glasgow and one in Dundee. The fatal cases both of measles and of scarlet fever were below the average. The deaths referred to diseases of the respiratory organs in the eight towns, which had been 75, 57, and 44 in the three preceding weeks, rose again to 73 in the week under notice, and exceeded by five the number returned in these towns in the corresponding week of last year. The causes of 13, or 2·6 per cent., of the deaths registered in the eight towns during the week were not certified; in the 76 English towns during the same week the proportion of uncertified causes of death did not exceed 1·0 per cent.

---

[1] THE LANCET, August 3rd, 1907, p. 309.

HEALTH OF DUBLIN.

The annual rate of mortality in Dublin, which had declined in the four preceding weeks from 24·1 to 20·[illegible] per 1000, further fell to 19·3 in the week ending Sep[illegible]19th. During the first 12 weeks of the current quarter the death-rate in Dublin averaged, however, 19·8 per 1000; the mean rate during the same period did not exceed 12·5 in London and 13·0 in Edinburgh. The 146 deaths of Dublin residents during the week under notice showed a further decline of ten from the high numbers returned in recent weeks, and included 21 which were referred to the principal epidemic diseases, against numbers declining from 44 to 28 in the four preceding weeks. These 21 deaths were equal to an annual rate of 2·8 per 1000; the rate during the week from the same diseases did not exceed 2·1 in London and 0·4 in Edinburgh. Of the 21 deaths from these epidemic diseases in Dublin during the week under notice, 16 resulted from diarrhœa, three from measles, and one each from whooping-cough and "fever," but not one from scarlet fever, diphtheria, or small-pox. The deaths attributed to diarrhœa, which had ranged from 39 to 20 in the four preceding weeks, further declined last week to 16. The three fatal cases of measles also showed a marked decline from recent weekly numbers. The 146 deaths from all causes during the week included 31 of infants under one year of age and 36 of persons aged upwards of 60 years; the deaths of infants showed a further considerable decline, while those of elderly persons were somewhat more numerous. Four inquest cases and four deaths from violence were registered; and 56, or 38·3 per cent., of the deaths occurred in public institutions. The causes of two, or 1·4 per cent., of the deaths registered during the week were not certified; in London the causes of all but three of the 1280 registered deaths were duly certified, while in Edinburgh the proportion of uncertified causes of death was 2·6 per cent.

THE SERVICES.

ROYAL NAVY MEDICAL SERVICE.

THE following appointments are notified:—Staff-Surgeons: W. W. Keir to the *Albemarle;* and W. E. Gribbell to the *Shearwater*, additional, and on recommissioning. Surgeons: A. J. MacDiarmid to the *Indomitable;* and D. G. Addison-Scott to the Portsmouth Division R.M.L.I.

ARMY MEDICAL SERVICE.

Colonel Charles A. Webb retires on retired pay (dated Sept. 19th, 1908).

Lieutenant-Colonel John R. Dodd, from the Royal Army Medical Corps, to be Colonel, vice J. J. La Vettée de la [illegible]beterre Morris (retired) (dated Sept. 9th, 1908).

ROYAL ARMY MEDICAL CORPS.

[illegible]ant-Colonel Arthur M. Davies is placed on retired [illegible]

Major M. P. C. Holt, D.S.O., has been appointed to th medical charge of the troops who will embark at Southampto on board the transport *Plassy* on Sept. 29th for Bombay. Captain J. W. West has been appointed to Dublin a specialist in operative surgery. Captain J. Tobin, from th Northern Command, has been appointed to the Iris Command, to take charge of the Military Families' Hospita at the Curragh. Major M. P. Corkery has been appointe medical officer in charge of the Military Families' Hospita at Woolwich.

INDIAN MEDICAL SERVICE.

The King has approved of the following promotions amon officers of the Indian Medical Service:—Lieutenant t be Captain (dated Feb. 1st, 1908): Hugh Clive Buckley To be Lieutenants (dated Feb. 1st, 1908): Rober Knowles, Wilfrid Edward Brierley, James Burne Lapsley James Alfred Shotten, Robert Beresford Seymour Sewell Charles Henry Fielding, William Linton Watson, Franci Romney Coppinger, Arthur de Courcy Cranstoun Charles Wilfrid James Simpson, Frederick Stevenson, James Willian [illegible] Madan Lal Puri, Saty [illegible] Townsend.

[illegible] retirement of the following officers:—Colonel Thomas James Hackett Wilkins (date June 30th, 1908); Lieutenant-Colonel Robert Pemberto [illegible]ated July [illegible], 1908); Lieutenant-Colonel George Henr Bull (date[illegible] July 1st, 1908); Lieutenant-Colonel Henr Armstrong (dated June 30th, 1908); Lieutenant-Colone Frederick Fitzgerald MacCartie, C.I.E. (dated June 30th 1908); and Lieutenant-Colonel John William Unthank Macnamara (dated July 12th, 1908).

TERRITORIAL FORCE.

Royal Army Medical Corps.

The undermentioned officers, from the Adjutancies of units of the Royal Army Medical Corps (Volunteers), to be Adjutants of Schools of Instruction for the residue unexpired of their tenures (dated April 1st, 1908): Major Alexander James MacDougall, Captain Harold Percy Waller Barrow, Captain Edgar Thomas Inkson, V.C., and Captain Langford Newman Lloyd, D.S.O.

DEATHS IN THE SERVICES.

Brigade-Surgeon Robert Lidderdale, late Bengal Medical Service, on Sept. 9th, at Torquay, aged 73 years. He entered the service in 1858, was promoted surgeon in 1870, surgeon-major in 1873, and brigade-surgeon in 1885. He was appointed superintendent of the Vaccination Department for Bengal in 1869 and sanitary commissioner for the Dependency in April, 1880. He retired in 1889.

IMPERIAL YEOMANRY.

Berks: Surgeon-Major John H. Waters resigns his commission, with permission to retain his rank and to wear the prescribed uniform (dated March 31st, 1908).

VOLUNTEER CORPS.

Rifle: 1st Volunteer Battalion, The Northumberland Fusiliers: Surgeon-Lieutenant Thomas Woodman *resigns his* commission (dated March 31st, 1908). 4th Volunteer Battalion, The Royal Fusiliers (City of London Regiment): The undermentioned officer resigns his commission (dated March 31st, 1908:—Surgeon-Lieutenant Henry C. Nicholls. 2nd (Berwickshire) Volunteer Battalion, The King's Own Scottish Borderers: Surgeon-Lieutenant James Marr resigns his commission (dated March 31st, 1908). 3rd (The Buchan) Volunteer Battalion, The Gordon Highlanders: Surgeon-Lieutenant-Colonel Andrew Mitchell is granted the honorary rank of Surgeon-Colonel (dated March 30th, 1908). The undermentioned officer resigns his commission, with permission to retain his rank and to wear the prescribed uniform (dated March 31st, 1908): Surgeon-Lieutenant-Colonel and Honorary Surgeon-Colonel Andrew Mitchell. 26th Middlesex (Cyclist) Voluntary Rifle Corps: The undermentioned officer resigns his commission (dated March 31st, 1908): Surgeon-Captain Percy J. Edmunds.

WESTON-SUPER-MARE HOSPITAL.—The annual house-to-house collection by members of the local friendly societies, which was recently held at Weston-super-Mare, resulted in £52 being raised for the funds of the Weston-super-Mare Hospital.

ascites. The liver was large and hard and the spleen was slightly enlarged. The patient's medical attendant supplied the following history. He first saw the patient on July 20th, 1906, when he found considerable ascites and a slightly developed collateral circulation. The patient admitted that he took two or three litres of wine daily. Paracentesis yielded 12 litres of citrine fluid. An absolute milk diet and iodide of sodium were prescribed, but the ascites recurred and repeated paracentesis was necessary. Up to January, 1907, this was performed nine times; the quantity of fluid obtained varied from 13 to 18 litres. After that the fluid was more slowly reproduced, paracentesis was performed at longer intervals, and the quantity of fluid obtained diminished. At the same time the subcutaneous abdominal veins gradually enlarged. At the period when the ascites was great an umbilical hernia appeared, but when the ascites diminished the hernia nevertheless continued to increase. On May 28th the hernia became strangulated. The sac was opened and the hernia was reduced. The patient completely recovered his health. When seen again, in November, 1907, the liver was large and the subcutaneous abdominal veins were still more developed but there was no trace of ascites. He returned to work but resumed his intemperate habits. In March, 1908, he had acute bronchitis which was followed by the pleural effusion mentioned above. The operation for empyema was performed but the patient was in an exhausted and infected condition and succumbed on April 18th. At the necropsy the veins forming the collateral circulation in the abdominal wall were found for the most part to be larger than the radial artery. They almost all seemed to converge to two large varicose trunks which originated in the epigastric region and ran obliquely upwards to terminate in the first part of the axillary veins. In the sheaths of the recti muscles were numerous orifices from which large veins emerged. A huge vein ran from the suspensory ligament of the liver and emptied into the left side of the subcutaneous plexus. The posterior wall of the sheaths of the recti also showed numerous orifices for the passage of veins which traversed the muscles to the subcutaneous plexus. The omentum was adherent to the abdominal wall for a considerable extent. This union was intimate in the umbilical region above and below the cicatrix of the herniotomy, for a surface 15 centimetres broad and 12 centimetres long. The omentum contained numerous varicose veins which were found to be those which traversed the recti muscles. There was a much developed subphrenic venous plexus which received veins from the phrenico-colic and phrenico-splenic ligaments and œsophagus, and which terminated in two large trunks opening into the vena cava. At the same meeting M. Chauffard also related two cases of spontaneous epiplopexy which he described as a "physiological justification" of Talma's operation.

SPORT AND MEDICATION.

THE "doping" of racehorses, a subject discussed in these columns in July, 1901, is said to be better understood in America than in England. It is regarded here as dishonourable and is indeed a criminal offence, but it is sufficiently known among us to have inspired a sporting author to write fully on the subject. Mr. Nathaniel Gubbins's book, which appeared some seven years ago, described two kinds of "dopes," according to one of which a horse is drugged with opiates or even purgatives to lose a race, and according to another is so treated sometimes with subcutaneous injections of from 10 to 12 grains of cocaine as to run at an abnormally accelerated pace. This latter kind of "dope" is perhaps the descendant of an ancient theory, according to which all animals connected with sport were liable to be medicated in order to fit them for the better performance of their duties. Hawks and falcons, for instance, were anciently the victims of ferocious drugging from the effects of which they frequently fell ill or died. Sir Thomas Browne, in his "Tract of Hawks and Falconry, Ancient and Modern," gives curious details of the treatment of these birds. Down to his times, if not later, it seems to have been a common practice to bleed them or treat them to vapour baths. To improve their sight they were seared "under the inward angle of the eye," and pepper and nettles were administered in order to enhance the hunting instinct, just as Spanish bulls are given hot mashes or otherwise excited before a bull-fight, and as cocks, where cock-fighting is prevalent, are specially prepared for the fray. A hawk or an owl to Sir Thomas Browne was evidently a *corpus vile* on which to make experiments in medication at large. For scab, he says, I have safely given six or eight grains of *mercurius dulcis* unto kestrils and owls, as also crude and current quicksilver, as well as pellets of silver and lead for the cure of worms. Quite recently it was proposed that athletes should be "doped" with oxygen before running or diving, and during the latest attempt to swim the Channel the performer at the end of his great effort is reported to have been receiving administrations of oxygen every quarter of an hour. The propriety of this sort of thing has been much discussed and we believe that the feeling of English sportsmen is hostile to it. An athletic feat achieved under medication cannot be compared, at any rate, with one performed without such accessories. It is a question, however, whether in certain contingencies "doping" of a kind is not permissible. An Englishman in India, for instance, who finds that his syce has sponged a horse's nose with opiated water in order to enhance the creature's endurance during a long journey is confronted with a very nice question in ethics. Sir Thomas Browne would have commended the syce.

THE EXERCISING OF INSANE PATIENTS.

PUBLIC attention has of late been drawn to an unfortunate state of affairs at Epsom and one of which the inhabitants of that pleasant town bitterly complain. During the last few years it has so happened that the vicinity of Epsom has afforded sites which, coming into the market, have been acquired and utilised by the London County Council for the purpose of the erection of the enormous asylums made necessary by the large increase in the insane population which has been one of the most perturbing features of the last few decades. We have always regretted this massing of insane patients in a comparatively small area and felt no surprise when Lord Rosebery in a letter to the *Times*, not long since, uttered a protest against the erection of yet another huge institution. The spectacle of suffering is never an agreeable one, and we have little doubt that if the patients in any general hospital were turned out for an occasional airing in large numbers we should hear that the spectacle was a ghastly one and calculated to scare the women and children of the neighbourhood. But in the case of mental disorder there is in addition to the painful spectacle of disease the added horror which attaches itself in the popular imagination to the idea of the "raving lunatic" and his supposed dangerous character. That in fact any member of a "walking party" is a dangerous lunatic we find it impossible to believe. No superintendent, however anxious to satisfy the proclivities of the Commissioners in Lunacy for a *minimum of restraint*, is in the least likely to permit a patient who is addicted to homicide or to assault and battery to go out with a walking party or to be without the strictest surveillance even while in the asylum itself. But apart from the idea of possible danger to the public, there

practically a teetotaller. I am, Sir, yours, &c.,
Wimpole-street, Sept. 21st, 1908. CHAS. MERCIER.

ON CHRONIC MORPHINISM AND ITS TREATMENT.

To the Editor of THE LANCET.

SIR,—The article which appeared in your issue of Sept. 12th on Chronic Morphinism by Professor Gamgee is highly instructive and is certainly the best contribution on that subject which I have read. Several theories have been propounded as to the cause of the distressing phenomena which follow abstinence from morphine in cases of chronic morphinism, but in my opinion Professor Gamgee's is by far the most sound. In regard to these symptoms and their treatment there are a few remarks I would like to make. During the last seven years I have treated for chronic morphinism 52 cases and therefore have some little knowledge of the subject. In regard to the symptoms that affect the nervous system I agree with Professor Gamgee, but in regard to the circulatory, respiratory, and gastro-intestinal my experience compels me to differ slightly. The intense cardiac dyspnœa which he speaks of I have not met with except in one case where the patient had been taking 80 grains of morphine per day before coming to me, and it took six months before the drug was entirely stopped. In regard to the gastro-intestinal symptoms, nausea, vomiting, and gastro-intestinal catarrh, these I have not found common, and when they have arisen I have found no difficulty in treating them, except when the patient has been in the habit of taking the morphine by the mouth. Constipation is as a rule present while the patient is taking the drug, and this may persist for some time after the drug has been cut off; strong purgatives may have to be used whilst the patient is taking morphine, but it is unwise to give these when the morphine is stopped. Enemata and mild laxatives are safer methods, bismuth subnitrate may also be given; with careful management I have always found these symptoms disappear.

In regard to treatment Professor Gamgee designates the sudden withdrawal of the drug as the English method. I do not admit that this is the English method; it may be the method adopted by English asylums, but certainly not by the different sanatoriums or retreats which make the treatment of morphinism, narcomania, or inebriety their special branch of medicine. I myself have invariably treated chronic morphinism by the slow reduction method. Professor Gamgee gives the time of from six to ten weeks in effecting this. This as a rule is too short, the average time being 13 to 16 weeks, and I have had cases which have taken over 20 weeks before the drug was abolished so as to avoid severe suffering and mental distress. I am quite aware that there is such a thing as syringe mania, but I find it far more satisfactory to continue the use of the hypodermic syringe till the last dose is given and even afterwards, when only a saline solution is injected. Giving it by the mouth and leaving off the syringe I have found adds to my difficulties. In regard to the nervous system symptoms—(*a*) Insomnia. After the drug has been cut off there is no doubt insomnia is one of the commonest symptoms complained of by the patient. I agree with Professor Gamgee in finding veronal extremely useful but seven grains is of little use; double that dose is required as a rule to combat this symptom and this drug must be slowly reduced or else insomnia is apt to return. (*b*) Uncontrollable restlessness. This is by far the most common symptom and I think the most trying to the patient, the constant twitching of the legs or arms, or as Professor Gamgee more aptly calls it the "fidgets" in the extremities are very trying and distressing to the patient. I have used for the treatment of this with marked success a preparation containing acetanilide two grains, caffeinæ citras five grains, sod. bicarbonate three grains. This remedy has succeeded when everything else has failed. (*c*) Maniacal and suicidal symptoms are rare but delirium and delusions are common; these as a rule pass off with ordinary treatment.

Professor Gamgee does not lay sufficient stress on the danger of administering alcohol either when the quantity of the drug taken by the patient is being reduced or has been cut off. In my experience I find that alcohol aggravates all these symptoms, and I would like to add [illegible] recovered alcohol as a beverage ought to be avoided. In nearly every case in which relapse has occurred, after having been successfully treated, I find that the use of alcohol started the craving for morphine.

I quite agree with Professor Gamgee in strongly condemning any attempt to cut off the patient suffering from chronic morphinism from the drug at once. It is almost criminal treatment, and I also agree with him that these patients should only be dealt with in a place where treatment can be thoroughly carried out—that is to say, where the hygiene is good, the air bracing, a proper nursing staff kept, and the patient is under the supervision of a medical man who has made a special study and has practical experience of this subject. Professor Gamgee does not refer to the after-treatment to prevent relapse. If patients, after their chronic morphinism is cured, would remain under supervision for a considerable time, say six to 12 months, there would be fewer relapses. A long period would not only give them time to build up their physical strength and establish their general health but would also give them more brain power in resisting [illegible] habit.

I [illegible]

JOHN Q. DONALD, L.R.C.P., L.R.C.S. Edin.,
Colinsburgh, Fife, N.B., Sept. 17th, 1908.

TO MEDICAL FREEMASONS.

To the Editor of THE LANCET.

SIR,—May I once again, through the medium of your widely read columns, appeal to medical men, and medical Freemasons in particular, for votes for the Masonic schools? At the forthcoming elections in October there is only one medical candidate for the Royal Masonic Institution for Boys, William Henry Collins, son of William C. G. Collins, formerly physician and surgeon, Bath. As there is no medical candidate for the Royal Masonic Institution for Girls votes for that institution can be exchanged and are equally valuable. Votes for either institution will be gratefully received and acknowledged by me.

I am, Sir, yours faithfully,
WILLIAM WILSON,
Secretary, St. Luke's Medical Lodge of Instruction.
184, Goldhawk-road, W.

RHUS TOXICODENDRON AND ARNICA.

To the Editor of THE LANCET.

SIR,—Your annotation on the subject of rhus toxicodendron in THE LANCET of Sept. 19th, p. 887, interested me, because during the last 12 months I have had under my care two cases of dermatitis which were caused by the climbing variety of this plant. Application of a lotion, containing acetate of lead and tincture of opium, gave so little relief that I resorted to a solution of picric acid (picric acid, grs. 4; sp. vini meth., min. 60; aq. destill., ad 1 oz.).

Some years ago I was called to see a woman who was suffering from a most severe form of dermatitis. She had sprained her wrist and her hostess, a keen amateur homœopath, had applied bandages soaked in arnica lotion, with the result that the patient's hands, wrists, and forearms were inflamed and covered with blisters. Not knowing an antidote for the local effects of arnica we decided to treat the case as a severe scald and used picric solution with very good result. The skin lesions produced by rhus toxicodendron and arnica resemble one another very closely, and the remedy which had acted well for arnica proved equally efficacious for rhus toxicodendron. The solution was applied in the form of compresses, where these could be easily kept in position by a light bandage, and to the parts where this was inconvenient the lotion was applied frequently with a very soft camel-hair brush. It quickly relieved the pain and hastened the healing of the blistered surfaces. The only drawback is its vivid yellow stain which takes a few days to fade away. Some chemists are unwilling to keep picric acid in stock because of its dangerous explosive properties; the solution, however, is perfectly harmless.

As for the therapeutic uses of rhus toxicodendron I have found it of some value in the treatment of that troublesome symptom, nocturnal incontinence of urine. I have given the tincture in five-minim doses, combined with nux vomica and buchu, to a number of young school boys who were suffering from this weakness. It has certainly failed in a few very official until 1890 and is still used as a tonic, alterative, and diuretic. Blood-root, sanguinaria canadensis, is tonic, alterative, stimulant, and emetic, and was formerly official in the United States Pharmacopœia. The root of hydrangea arborescens has diuretic properties and was employed by the Cherokees and early settlers for urinary calculi. The root of Indian physic, porteranthus trifoliatus, was a popular remedy with the Indians on account of its emetic properties. This drug was official in the United States Pharmacopœia until 1880 and its action is said to resemble that of ipecacuanha. The root of wild indigo, baptisia tinctoria, is emetic and cathartic and may prove dangerous in large doses. It has stimulant, astringent, and antiseptic properties and has been used as a local application to sores and ulcers. The entire plant was official in the United States Pharmacopœia from 1830 to 1840. Crane's-bill root, geranium maculatum, is now official in the United States Pharmacopœia and is used as a tonic and astringent. The root of stillingia sylvatica, also official in the United States Pharmacopœia, has occupied a prominent position for more than a century as an alterative. The water-eryngo, eryngium yucci folium, is an old remedy for snake-bite and was official in the United States Pharmacopœia from 1820 to 1860. It is now employed as a diuretic, expectorant, and diaphoretic. In large doses it acts as an emetic and the root when chewed excites the flow of saliva. It is said to resemble senega in its action. American angelica root, archangelica atropurpurea, which was official in the United States Pharmacopœia until 1860, is used for its aromatic, tonic, stimulant, diuretic, and diaphoretic properties. The seeds are also employed medicinally. The root of black Indian hemp, apocynum cannabinum, is official in the United States Pharmacopœia and possesses emetic, cathartic, diaphoretic, expectorant, and diuretic properties. Pleurisy root, asclepias tuberosa, was much esteemed by the Indians and is official in the United States Pharmacopœia. It is used in some forms of disordered digestion and possesses diaphoretic properties. In affections of the lungs it promotes expectoration, relieves pain in the chest, and induces easier breathing. The leaves of stone-root, Collinsonia canadensis, are used by country people as an application to bruises. The root is employed for its tonic, astringent, diuretic, and diaphoretic properties. Culver's root, leptandra virginica, is official in the United States Pharmacopœia and is used as an alterative and cathartic and in diseases of the liver. The root of queen of the meadow, eupatorium purpureum, has astringent and diuretic properties and was official in the United States Pharmacopœia until 1840. It is interesting to note that elecampane, which was formerly grown in large quantities in England, is much used in the United States in affections of the respiratory organs, disorders of the digestion, hepatic troubles, catarrhal discharges, and in skin diseases. The root of echinacea augustifolia is said to be alterative, diaphoretic, and sialagogue. The Indians used the freshly scraped roots for the cure of snake-bite. Echinacea came into notice in England about seven years ago in the treatment of tuberculosis but it failed to justify the hopes that were entertained of it. The roots of comfrey and burdock, plants common in England, are also used medicinally in the United States. Many of these drugs are very largely used in the United States, both officially and otherwise.

STRICTURE OF THE URETERAL ORIFICE.

IN the *Australasian Medical Gazette* of July 20th Dr. H. C. Hinder has reported a curious case of ureteral obstruction which shows the value of cystoscopy in doubtful urinary conditions. A healthy man, aged 33 years, went to hospital complaining of left-sided attacks of abdominal pain which occurred at varying intervals and were at times accompanied by diarrhœa. The pain came on suddenly and was very severe and often accompanied by vomiting. It was felt most intensely in the left groin and extended thence into the renal region and down to the testicle which was drawn up. The pain was paroxysmal and gradually ceased after a few hours. During the attack no blood was observed in the urine but it was often very turbid immediately after it was passed. There was never pain on micturition until the last attack, when there was a considerable amount. The patient never observed that he passed a calculus. There was some frequency of micturition during the attacks but this symptom was not marked. When he went to hospital there was neither sign nor symptom. Ureteral calculus, which had been passed at the last attack, was diagnosed. A skiagram was twice taken with negative result. As the patient felt quite well he was about to be discharged when another attack occurred. Cystoscopy then showed that while the clear urine was spouting from the right ureter nothing was emitted from the left, which for a distance of three-quarters of an inch was distended and of a dull red colour. Per rectum this swelling could just be felt. Suprapubic cystotomy was performed. The swollen end of the ureter in the relaxed bladder was not well marked and without previous information might easily have been overlooked. But bimanually the swelling could easily be felt; it was so tense and hard that it was thought to contain a stone. The ureter was slit up and to Dr. Hinder's surprise about half a drachm of foul pus escaped and was followed by some turbid urine. The flaps of the incised ureter were stitched back to the bladder wall to keep the opening patent and the bladder was closed except for a suprapubic drain. Recovery was uneventful. About four months later another attack of renal colic occurred, after which a calculus of the size of a grain of wheat was passed. It is hard to say why the orifice of the ureter became blocked. Dr. Hinder thinks that it was probably injured during the passage of a sharp stone and that the resulting cicatrisation caused a constriction at the ureteral orifice.

A CHAUFFEUR AND THE COCAINE HABIT.

AN interesting and somewhat disquieting side-issue arose in a case recently heard before Mr. Francis at the Westminster police court, the defendant being charged with obtaining food and lodging under false pretences. It was stated that he had been addicted to the cocaine habit for years and a supply of that drug and two hypodermic syringes were found upon him at the time of his arrest, when, according to medical evidence, he was under its influence. Police evidence proved that in spite of his wretched condition he had taken out a motor-driver's licence during the past year and had had two serious accidents while driving. Mr. Francis expressed his surprise and hoped that information would be given to the authorities which would prevent the renewal of the licence. Mr. Titterton (the chief clerk) remarked that in the present state of the law he did not know how the licence could be refused. The case presents an obvious parallel to that of an engine-driver being taken suddenly ill on the foot-plate which was discussed somewhat freely at the beginning of the year. In this instance it is even harder to suggest an adequate remedy. In a recent letter to the *Royal Automobile Club Journal and Motor Union Gazette* Dr. H. E. Bruce-Porter called attention to the facts that the Competitions Committee has decided that all the drivers in the "Four-Inch" Club race shall be medically examined before being allowed to compete, and that all the drivers of the Motor-cab Company are examined for physical fitness. He hopes that ultimately all bodies issuing licences to drive will require a certificate to the effect "that the applicant is not suffering from any disease which renders it dangerous to and now three kitchens are in existence in Chelsea at which dinners are provided, not only for nursing but also for expectant mothers. One of these is in the Salvation Army hall in Denyer-street; another in St. John's Mission Hall, World's End; and the third and central kitchen in Sydney-street, whence it was removed from its former quarters in Arthur-street. It has been found from experience that it is more convenient for the mothers that the kitchen should be near their homes. It is therefore proposed as the scheme develops not to move into larger central premises, but rather to multiply the small centres. Suitable cases to benefit by the scheme are selected by responsible persons—i.e., by a nurse, a district visitor, or a lady inspector. The dinners consist of meat and vegetables with cocoa, with occasional interludes of fish, soup, or pudding. The meals are provided on five days of the week, the exceptions being Sunday and Monday, because the poor nearly always contrive to provide a good meal on Sunday, enough of which will be left to feed the family on Monday also. The dinners are served from 12 to 1.30 and women can attend two or three months before their confinement and up to the time that the baby is nine months old if they continue nursing. A short time ago I paid a visit to the central kitchen in Sydney-street, Chelsea, during the dinner hour and found 15 women, for the most part young and with infants, enjoying an excellent meal in a good-sized room in the basement next to the kitchen. At this kitchen an average of 30 dinners were provided daily in July and at the St. John's Mission kitchen about 15 dinners were supplied daily. The kitchen in Denyer-street was closed during the summer months. The following summary of the work done will show the value of Mrs. Gordon's labours and those of her collaborators. There were served 6697 dinners during the year 1907, while between Jan. 1st and June 30th, 1908, 4936 dinners were provided. The cost of the undertaking for 1907 was £150 and the cost of each dinner was approximately 4½*d.* The mothers and infants whom I saw seemed healthy and I was informed that in several instances the mother was not able to suckle the child when she first attended, but that after she had received good nourishment for a time she was able to do so. I was also told that in Chelsea the difficulty met with so frequently of persuading mothers to suckle their infants was greatly lessened owing to the fact that there are no large factories in the borough in which women are employed. Consequently the majority of the women are at home all the day, or if they do go out to work it is only to perform some light labour which will not keep them long from their homes. The infants of the mothers who are being fed are inspected by a medical man and weighed every week, and the mothers take the greatest interest in the weight of their infants. The main differences between the Coullet restaurants in Paris and Mrs. Gordon's kitchens in Chelsea are that at the latter the meals are not free, though the price is so very moderate as 1*d.*, that the women must be recommended as fit cases, and that they must attend regularly having once been recommended. This comes to mean that the women assisted in Chelsea will be of a respectable class, while in Paris a helping hand is given to any woman who applies for it, pregnancy or nursing being the only qualifications.

The next and most ambitious scheme in aid of the proper bringing up of infants in London was inaugurated in St. Pancras parish in the early part of 1907 and has already been alluded to in THE LANCET.[1] Dr. J. F. J. Sykes, medical officer of health of St. Pancras, has laboured long and hard to encourage the natural feeding of infants in the district under his sanitary supervision and the St. Pancras School for Mothers is a philanthropic attempt to further the efforts now being made by the municipality. The St. Pancras School for Mothers is based partly upon the principles of the School for Mothers at Ghent but modified and adapted to the needs of the St. Pancras district, embracing as well the system in force in Chelsea of feeding expectant and nursing mothers. The municipal and philanthropic schemes in St. Pancras for the reduction of infantile mortality and sickness are worked in unison to some extent. The official lady health visitor of St. Pancras, having access to the notifications and registrar's returns of all births occurring in the borough, is able to select cases within easy distance of the school which in her opinion might be benefited by the advice and treatment given there. The parents are informed by her of the objects of the school and she tells them when to attend. The school for mothers has its quarters on the ground floor and basement of a good-sized building in Chalton-street, Euston-road, N.W. I visited the school and I saw expectant and nursing mothers at dinner, and inspected the whole premises and received all the information which I asked for in regard to the working of the scheme from the lady superintendent. The work is divided into the following departments: 1. Infant consultations. 2. Dinners for nursing and expectant mothers. 3. Educational classes for mothers. 4. Provident maternity club. 5. Home visiting. 6. Fathers' evening conference. The titles indicate the kind of work done under each heading.

1. The infant consultations form a medical department for the treatment of infants under 12 months of age. Miss Dora E. L. Bunting, M.B., B.S. Lond., who acts as honorary medical officer to the charity, attends at the school on two afternoons of the week to examine babies and to give advice as to the feeding, clothing, and general management, as well as to assist the mothers in any medical matters.

2. To come to the dinners, the rules are the same with regard to the feeding of expectant and nursing mothers as are in force at Chelsea, except that the charge for the dinner is 1½*d.* instead of 1*d.* The dinners at St. Pancras are provided at an average cost per head for actual food of less than [illegible]½*d.*, and this is probably much the same as the cost at Chelsea, where the 4½*d.* covers all the expenses and not only the actual food. The mother pays 1½*d.* per meal when able; in some cases private individuals or charitable associations bear the cost, while in a few other cases meals are provided gratuitously if after investigation the cases are found to be deserving ones. Many of the expectant or nursing mothers are said to be almost starving when admitted to the meals, and the lady superintendent informed me that the results to mothers and children from substantial and nourishing food have been most gratifying. The cleanliness of the building, the plentiful supply of food, and the general well-being of the regular attendant, can hardly fail to strike every visit

3. The educational classes for mothers have more or less succeeded in their object, but exactly how far it must be always difficult to say. The diffusion of information among uneducated persons is difficult and disappointing, and too much must never be expected from it. The knowledge is being diffused, but the actual results may not be appreciable for some time. On Thursday afternoon of each week a cookery class is held at the school, at which women are taught how to prepare and to cook simple nourishing dishes. It is well known that this kind of teaching is greatly needed in all parts of England; in many provincial and country districts county and municipal authorities have been trying to supply it. The result is that the poor housewives of London are more behindhand in domestic economy than many of their country compeers. A knowledge of the manner in which to prepare and to cook cheap and nourishing food has been found generally absent in St. Pancras, and this is a matter which the school is trying to alter. Simple dressmaking is also taught. On Tuesday evenings women are invited to practise cutting out at the school and on Wednesday afternoons, while mothers make garments for their children, elementary lectures are given inculcating the value of fresh air and cleanliness; the meaning of economy with respect to food; and the various lessons to be learnt for the management of pregnancy and the care of infants. This class is said to be most successful in its results; the mothers manifest great interest in the proceedings and willingly undergo catechism on the previous lesson, showing that they certainly absorb a large amount of extremely valuable information. This information spreads. The women of the working class are gregarious in their habits—is it not considered by them a mark of gentility "to keep yourself to yourself"?—and while they are slow to learn, when once they become impressed with certain simple truths—as the good effects of the open window, the healthfulness of the daily bath, the injurious influence of "comforters," and the importance of breast-feeding—they come to regard these things as articles of faith and to disseminate the gospel throughout the area in which they and their acquaintances live.

4. A provident maternity club has been instituted in connexion with the school, by the agency of which money is laid

---

[1] THE LANCET, June 15th, 1907, p. 1665.

right through the Acts, and are found in the Acts and the Gospel equally." This last line of argument might be strengthened by consideration of the treatment applied by the Good Samaritan to the man wounded by brigands—to wit, the bandage saturated with wine and oil, a practice for which more than a century later than St. Luke there is the authority of Galen. *Sed haec hactenus.* It will, indeed, tax the resources of the Higher Criticism to shake the conclusion of latest finding of the orthodox that "we are fully warranted in affirming that the evidence of the books themselves entirely coincides with the verdict of early Church history regarding the authorship and that there are few facts in literature better established than this—that St. Luke, the Beloved Physician, the companion and fellow-labourer of St. Paul, is the author of our Third Gospel and the Acts."

LUMBAGO OR RUPTURED MESENTERY.

Dr. De Busscher and Dr. Schoenfeld at a recent meeting of the Ghent Medical Society mentioned several cases where injuries followed by pain in the loins which was apparently of the nature of ordinary lumbago proved to be due to a rupture of *the mesentery, this being made evident by* effusion into the hypogastric region. In one case this effusion was thought to denote tuberculous peritonitis, and tuberculin was injected for diagnostic purposes. There was no reaction and the patient ultimately recovered under rest and an abdominal belt. Mesenteric injury is occasioned by violent exertion, such as lifting a heavy weight, the patient having previously filled his lungs by a very deep inspiration, thus fixing the origins of the shoulder muscles, and at the moment of supreme effort involuntarily contracting the diaphragm and abdominal muscles, thus tearing the mesentery. Probably operative measures are rarely required, the effusion becoming reabsorbed with the help of an abdominal bandage, the patient being, of course, kept at rest. These cases are of considerable interest as questions of prognosis as well as of diagnosis frequently occur in connexion with the insurance of workmen, and disputes as to the nature and duration of cases of "lumbago" are by no means uncommon. Of course, in examining them care must be taken that the bladder and sigmoid flexure are empty.

THE autumn meeting of the South-Eastern Division of the Medico-Psychological Association will be held, by the courtesy of Dr. F. A. Elkins, at the Metropolitan Asylum, Leavesden, on Tuesday, Oct. 6th. Dr. Elkins will entertain the members to luncheon, after which the meeting of the divisional committee will be held, followed by the general meeting. The members will dine together after the meeting at the Café Monico, Piccadilly-circus, London, W., at 6.45 P.M., provided that a sufficient number agree to dine. (Dinner 5*s.*, exclusive of wine. Morning dress.)

A TELEGRAM from the Governor of Mauritius received at the Colonial Office on Sept. 18th states that for the week ending Sept. 17th there were 7 cases of plague reported and 5 deaths from the disease.

THE discussion upon Human and Bovine Tuberculosis at the International Congress on Tuberculosis at Washington is to be opened by Professor Robert Koch.

BRISTOL MEDICAL SCHOOL.—The annual Bristol medical students' dinner will be held at the Royal Hotel, Bristol, on Oct. 1st. Major H. C. Thurston, C.M.G., R.A.M.C., will be the president and Sir Rubert Boyce, F.R.S., the guest of the evening. Tickets (5*s.* each) may be had on application to the honorary secretary, Bristol Royal Infirmary.

NOTE ON FRENCH AND GERMAN FOR MEDICAL STUDENTS.

BY WILLIAM OSLER, M.D. OXON. & McGILL, F.R.S.,
REGIUS PROFESSOR OF MEDICINE, OXFORD.

AT the beginning of each academic year I am in the habit of sending to the undergraduates in medicine a memorandum on the importance of the study of French and German. A good working knowledge of these languages may be very easily obtained. The plan recommended is: 1. The student provides himself with elementary text-books in French and German on the subjects at which he is working. With a very slight knowledge of grammar and with the aid of a dictionary he can very quickly learn to read such books intelligently. 2. For the senior student reading classes are formed, particularly in physiology, and of these Miss Florence Buchanan, at The Museums, has had charge, and she has been most helpful. 3. In the long vacation students are urged to spend a semester at one of the French or German medical schools. Through the courtesy of the professors in charge I have found it very easy to get places for men in the laboratories. Lastly, the senior students are recommended to get into the habit of looking over one of the French or German journals each week. With a little persistence and with a very slight expenditure of time a medical student should have both these important languages at his command before graduation.

The following list of books kept by Messrs. Blackwell and Co. and Messrs. Parker and Son, Oxford, may be useful:—E. Aubert: "Phénomènes de la Vie," 1*s.* 8*d.*; "Premières Notions de Chimie," 1*s.* 6*d.* J. Joubert: "Traité d'Électricité," 6*s.* 4*d.* H. de Meric: "Dictionnaire des Termes de Médecine," Part I. (English-French), 5*s.*; Part II. (Français-Anglais), 4*s.*; Two Parts in one volume, 7*s.* 6*d.* F. Schenck and A. Grueber: "Leitfaden der Physiologie," 5*s.* 5*d.* Kienitz-Gerloff: "Physiologie und Anatomie des Menschen mit Ausblicken auf den ganzen Kreis der Wirbeltiere," 3*s.* E. Cohen: "Vorträge für Aerzte über physikalische Chemie," 8*s.* J. E. Reynolds: "Leitfaden zur Einführung in die Experimentalchemie," four vols.: (1) Einleitung, 1*s.* 5*d.*; (2) Metalloide, 2*s.*; (3) Metalle, 2*s.*; (4) Chemie der Kohlenstoffverbindungen oder organische Chemie, 2*s.* 8*d.* P. Blaschke: "Medicinisches Wörterbuch in deutscher, französischer und englischer Sprache in einem Alphabet," 6*s.* Hugo Lang and B. Abrahams: "German-English Dictionary of Terms used in Medicine and the Allied Sciences," 15*s.* H. G. Fiedler and F. E. Sandbach: "A First German Course for Science Students," 2*s.* 6*d.*; "A Second German Course for Science Students," 2*s.* 6*d.* W. A. and E. E. Osborne: "German Grammar for Science Students," 2*s.* 6*d.*

Oxford.

NOTES ON THE LACTIC FERMENTS AS THERAPEUTIC AGENTS.

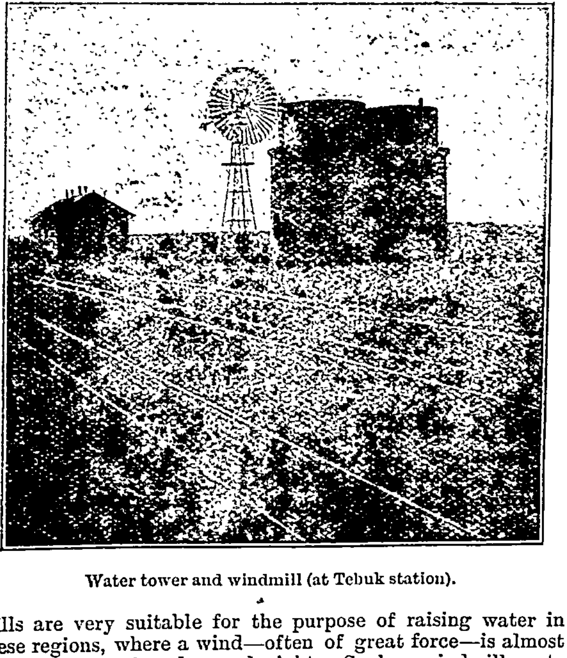
BY FRÉDÉRIC S. MASON, B.Sc. (FRANCE), M.P.S.

SINCE Metchnikoff began to publish his investigations and the butter-milk theory became popular much clinical evidence has been forthcoming. The object of this paper, however, is not to question or to affirm the truth of the lactic-acid theory but to point out some of the fundamental principles which underlie Metchnikoff's reasonings and which appear to have been overlooked in the enthusiasm with which the medical profession and the general public are taking to the buttermilk craze. Neither is there any intention to specify any particular bacteria for curdling milk, since it is well known that the property of producing lactic acid is common to a vast number of micro-organisms. As a matter of fact, many saprophytes and pathogenic bacteria which fall into milk on exposure to the air are just as capable of giving rise to lactic fermentation under favourable conditions as the ferments maya, kephir, leben, &c., which have been so long in use amongst Oriental races. The latter, however, contain sufficient useful lactic-acid-forming bacilli to counteract those which give rise to toxins and secondary alkaline fermentation. The slight danger of even such pathogenic bacteria as the streptococcus, staphylococcus, typhoid bacillus, the spirillum of Asiatic cholera, &c., has been beyond Dat-el-Haj, the solitary station-building is constructed on almost the same plan though on a much smaller scale.

Meissner Pasha, the chief engineer for the construction of the railway, resides at Ma'an in a stone house built close to the station. He was unfortunately absent when the Commission passed through on its downward journey, having gone to the head of the line. On the return journey, however, two of our number separated here from the rest of the Commission who proceeded directly to Damascus; we made a rapid excursion to Petra and on returning to Ma'an we found that Meissner Pasha had come back. He was good enough to furnish me then, and since by correspondence, with much valuable information on many points connected with the problems which the Commission was called upon to solve.

The water-supply in the neighbourhood of Ma'an station is derived from a spring called Ain-el-Kelbé and from numerous wells. The [illegible] yards from the station; the water here [illegible] small stone cistern [illegible] This has no parapet round and [illegible] undoubtedly takes place. The spring yields about 25 tons of water a day; some of the water is carried from the spring by a conduit to a well close to the station. The soil here [illegible] to be composed of a mixture of calcareous stone and clayey earth below the surface of sand. The well is 18 metres deep; by the side is a steam pump which raises the water to two reservoirs of 100 tons each on the top of a stone tower close by. The pump can also be worked by a light metal windmill of what is called the American pattern, though this (and most of those elsewhere along the line) is of German origin. Similar water towers with steam pumps and windmills are found at many of the principal stations on the railway. These light windmills are very suitable for the purpose of raising water in these regions, where a wind—often of great force—is almost constantly blowing day and night. Such a windmill costs about £100, or, including the cost of putting up, about £120.

Fig. 2.

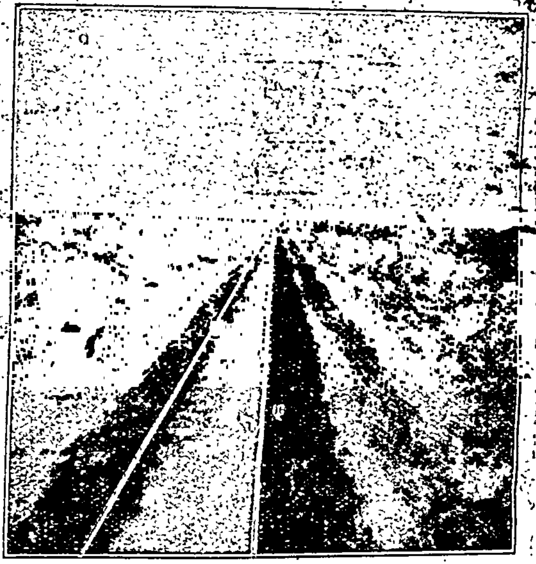


Water tower and windmill (at Tebuk station).

The well just described yields about 30 tons of water per day, to which must be added about 10 tons brought from Ain-el-Kelbé. There is a second well being dug 24 metres away from the first; here a layer of water was found at 10½ metres depth. A third well exists about 150 metres away in another direction; its depth is 15 metres and its yield about 50 tons. A fourth well has been sunk in the garden of Meissner Pasha's house; its depth is also 15 metres and it yields about 24 tons of water per day. Finally, a kilometre to the north of the station and about 100 metres from the line is a fifth well; it is said to be only 5 metres deep and to yield 50 tons per day.

It will be seen that there is no lack of water at Ma'an; but its quality is less satisfactory than its quantity. The water from the Ain-el-Kelbé springs gave the following results on analysis: Colour, faintly yellow; smell, faintly earthy; chlorine, 15·4; nitrogen—as nitrates 0·029, as free ammonia 0·003, as organic ammonia 0·005, total 0·037; oxygen absorbed by the permanganate process in three hours at 27° C., 0·0648; total hardness 15·08, permanent hardness 14·06; total solids, 56·4. All the preceding figures represent grammes per 100 litres, or parts per 100,000. The well waters of Ma'an were not analysed; they are said to be better than the spring water, but they contain much calcareous matter, tend to cause gastric disturbance, and are shunned by some officials on the line, who import their water from Amman 237 kilometres away.

Fig. 3.



The line across the desert.

The climate of Ma'an is cooler than is that of places further south; the thermometer never rises there, it is said, above 40° C. (104° F.). I noted there, at 1 P.M. on June 7th, a temperature of 33° C. (91·4° F.). Unfortunately no meteorological records exist at present for any of the places along the Hedjaz Railway, with the single exception of certain pluviometer readings kept by Meissner Pasha for the last year or two at Ma'an. He has kindly furnished me with the following readings, which show how scanty the rainfall is here:—

Rainfall at Ma'an.

It will be seen from these figures that in two years only some three inches of rain fell at Ma'an. Sand storms, which are very frequent and severe at some places on the line, are not common here; they occur perhaps three or four times in the year.

Ma'an had been suggested as a possible site for the future pilgrims' lazaret. There would be abundance of land suitable for the construction of such lazaret. Good building stone is found in considerable quantity; it occurs in large nummulitic lumps. The station buildings are extensive, and are mostly, if not all, built of this stone. There is a buffet and even an hotel at the station. I had occasion to stop a night

From a practical standpoint the dried bacilli are preferable to butter-milk, since they can be obtained by evaporation at a low temperature and their activity indefinitely preserved in hermetically sealed tubes. The economy of implanting milk from day to day with old butter-milk is not desirable, because of the possibility of the culture degenerating into a mixed culture, and since a 30 centigramme tablet of pure cultures will curdle a litre of boiled milk (when cooled to 40° C.) in about 12 hours, besides partially peptonising the milk proteid; the economy therefore is uncalled for. Equally good results, however, are claimed by the administration of the tablets of dry bacilli with or without milk. The amount of lactic acid obtainable with lactic ferments is only limited by the amount of saccharine matter present in the culture medium, for if the lactic acid formed is neutralised from time to time by calcium carbonate the bacilli continue to grow.

The lactic acid therapy has still some opponents on account of the somewhat sensational statements made and the literature on the subject leaves too much to the imagination; the writer hopes therefore that these considerations will explain the possibilities of the lactic acid bacilli in the treatment of many difficult gastro-intestinal diseases, the prevention of gout and rheumatism, and the long train of sequences leading up to nephritis, arterio-sclerosis, and pre-senility.

Paris.

REPORT OF THE ROYAL COMMISSION ON THE CARE AND CONTROL OF THE FEEBLE-MINDED.

II.[1]

THE next series of problems dealt with by the Commission is that connected with mental defect and crime, and the after-school life of feeble-minded persons in prisons, workhouses, casual wards, common lodging-houses, and shelters is considered. Dr. J. Scott, in an able *résumé* of the problems, states that during his connexion with the London houses of detention he has dealt with many feeble-minded persons who could not be certified as insane but who could not be fairly held responsible for their misdeeds. Many of these are such as have not been kept in any control by their parents and who have had but scanty education owing to the undesirability of their presence in the ordinary schools. They are only fit for unskilled labour and even for it are often too stupid or too wanting in application. They are frequently in trouble for breaking the law and being sent to prison, usually for short periods only, soon return to their mischievous ways. In prison they are not amenable to penal discipline or to reforming influences. They have but little self-respect and home ties do not weigh much with them, so that to many of them prison is a harbour of refuge where they are spared the trouble of getting food and lodging. Dr. Scott further adds that when such persons are at liberty their friends do not as a rule welcome them nor are they fit to take part in the struggle for existence. By their proneness to commit larceny, arson, indecent assaults on children, &c., they are a constant source of annoyance, expense, and danger. Many are unfit, without care and discipline, to lead inoffensive lives, and it is important to consider if any means can be taken to prevent these undesirables from producing their like. The evidence that came before the Commission is unanimously in favour of segregation or detention, in a large number of cases of mental defect, after the period of childhood. Such detention as is now practised is neither preventive nor reformatory. It has relation to the fact that an offence has been committed, but none to the fact that the offence was committed by a mentally defective person. Miss Dendy, honorary secretary of the Lancashire and Cheshire Association for the Permanent Care of the Feeble-minded, gave evidence to show how horribly disastrous are the results of leaving the feeble-minded at large, and quoted cases to show the evil uses to which such persons are put by unscrupulous relatives. Mr. Allen, chairman of the Special Schools Committee of the London County Council, thought that probably the bulk of the children who would go to the custodial homes never ought to go out into the world at all, and on leaving school should be drafted into colonies where they may be efficiently segregated. Dr. Ashby was of opinion that the large, unguarded, and unprotected class of idiot and imbecile children and older people for whom no supervision exists tend to an increase of the criminal and immoral classes. Dr. Whitwell said that the feeble-minded who were capable of a considerable degree of education were usually retained at home, at least until after puberty, but that at that time physical evolution taking place, in the absence of intellectual control, development was apt to result in acts of theft, cruelty, incendiarism, homicide, and various offences of a sexual or perverted sexual nature, and that under existing conditions education on the usual lines was so entirely erroneous as to result in the feeble-minded spending their lives alternately in the prison, the workhouse, and the asylum. Such as have had the advantage of having been in asylums for the feeble-minded lose on their discharge all the advantages of their training and sink by degrees to the workhouse. Dr. E. Marriott Cooke points out how those who have benefited most by the care and training which they have received and who seem to be the most promising are those for whom detention is especially required. While in the asylum they present a bright and intelligent appearance and perhaps have become, under supervision, to some extent self-supporting, but attempts to place such persons out in the world generally meet with failure and the individuals ultimately gravitate to the workhouse. Dr. T. S. Clouston in his evidence said he had come to the conclusion that feeble-minded young women in a large city were subject to overwhelming temptations and pressure towards sexual immorality. He found that it was the exception among a certain class for any of them not to have been sexually tampered with. Many of them had illegitimate children and at a very early age. He is of opinion that when illegitimate children are borne by such young women the chances are enormously in favour of their turning out to be imbeciles, or degenerates, or criminals. Mr. Legge, then inspector of reformatory and industrial schools, thought that every feeble-minded person should, on reaching a certain age, be examined, and if found to be suffering from mental deficiency such as might render him unfit to protect himself or not fully responsible for his actions, be segregated for an indeterminate period. Sir Edward Fry pointed out that in a ruder state of society little heed was taken of feeble-minded children and that many of them probably died at a comparatively early age, but that as we learn to think more tenderly of the inferior members of our race we seek to protect them from their calamities and to preserve their lives to the utmost. But in so doing we incur the responsibility of preventing the perpetuation of a low class of humanity, for otherwise the beneficence of one generation would become the burden and injury of all succeeding ones.

In the three years 1902 to 1904 3119 juvenile offenders passed through remand homes in London. Of these there were taken at haphazard 109 boys and 28 girls. Of the boys 37 were graded between "backward, slightly mentally deficient, and mentally deficient," and of the girls 16 were similarly classed. If these figures are fairly representative it may be said that a large number of juvenile offenders, in whom the connexion between mental defect and criminality may be observed in the earliest stages, come before the magistrates. But unfortunately no advantage is at present taken of this opportunity of dealing with the evil at its first manifestation. At a little later stage these unfortunates are sent to prison or are "bound over" or discharged. Unless certified as insane they cannot be detained. Even if treated as insane, which they can hardly be under the present law, on discharge to the workhouse the Poor-law medical officer and the magistrate at the workhouse may refuse certification and order of detention. There is no institution intermediate between the prison and the lunatic asylum to which they may be admitted. Of the prisoners at Pentonville it appears that about 100 a year were so far mentally affected as to be quite unfit for prison discipline. These represent the extreme cases which mostly drift to asylums. Besides these not less than 20 per cent. of the prisoners show signs of mental inefficiency. In the various local prisons of England and Wales the same state of affairs is to be found. In the year ending 1904 there were 145 prisoners who, although not certainly insane, were unfit for ordinary penal discipline by reason of mental deficiency. These did not represent the total number of the beyond Dat-el-Haj, the solitary station-building is constructed on almost the same plan though on a much smaller scale.

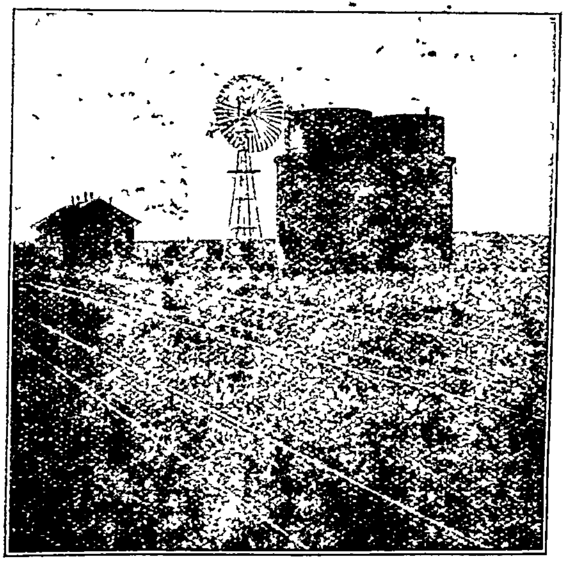
---

[1] No. I. was published in THE LANCET of Sept. 19th, 1908, p. 880.

Meissner Pasha, the chief engineer for the construction of the railway, resides at Ma'an in a stone house built close to the station. He was unfortunately absent when the Commission passed through on its downward journey, having gone to the head of the line. On the return journey, however, two of our number separated here from the rest of the Commission who proceeded directly to Damascus; we made a rapid excursion to Petra and on returning to Ma'an we found that Meissner Pasha had come back. He was good enough to furnish me then, and since by correspondence, with much valuable information on many points connected with the problems which the Commission was called upon to solve.

The water-supply in the neighbor [illegible]
is derived from a spring called [illegible]
numerous wells. The spring is abo [illegible]
station; the water here is gathered [illegible]
cor [illegible]
sur [illegible]
yie [illegible]
car [illegible]
stai [illegible]
of [illegible]
sand. The well is 18 metres deep; by the side is a steam pump which raises the water to two reservoirs of 100 tons each on the top of a stone tower close by. The pump can also be worked by a light metal windmill of what is called the American pattern, though this (and most of those elsewhere along the line) is of German origin. Similar water towers with steam pumps and windmills are found at many of the principal stations on the railway. These light windmills are very suitable for the purpose of raising water in these regions, where a wind—often of great force—is almost constantly blowing day and night. Such a windmill costs about £100, or, including the cost of putting up, about £120.

FIG. 2.

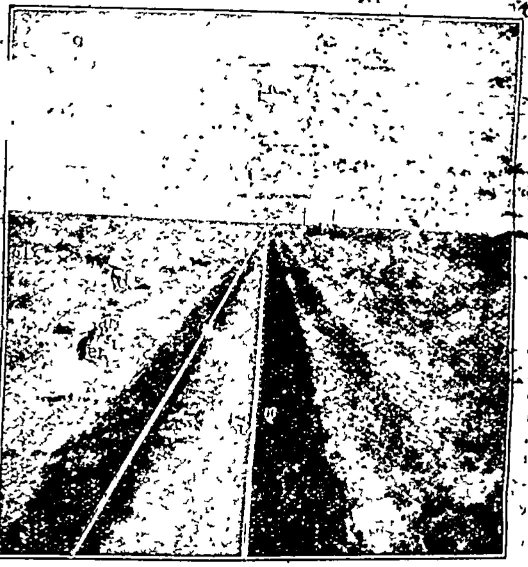


Water tower and windmill (at Tebuk station).

The well just described yields about 30 tons of water per day, to which must be added about 10 tons brought from Ain-el-Kelbé. There is a second well being dug 24 metres away from the first; here a layer of water was found at 10½ metres depth. A third well exists about 150 metres away in another direction; its depth is 15 metres and its yield about 50 tons. A fourth well has been sunk in the garden of Meissner Pasha's house; its depth is also 15 metres and it yields about 24 tons of water per day. Finally, a kilometre to the north of the station and about 100 metres from the line is a fifth well; it is said to be only 5 metres deep and to yield 50 tons per day.

It will be seen that there is no lack of water at Ma'an; but its quality is less satisfactory than its quantity. The water from the Ain-el-Kelbé springs gave the following results on analysis: Colour, faintly yellow; smell, faintly earthy; chlorine, 15·4; nitrogen—as nitrates 0·029, as free ammonia 0·003, as organic ammonia 0·005, total 0·037; oxygen absorbed by the permanganate process in three hours at 27° C., 0·0648; total hardness 15·08, permanent hardness 14·06; total solids, 56·4. All the preceding figures represent grammes per 100 litres, or parts per 100,000. The well waters of Ma'an were not analysed; they are said to be better than the spring water, but they contain much calcareous matter, tend to cause gastric disturbance, and are shunned by some officials on the line, who import their water from Amman 237 kilometres away.

FIG. 3.



The line across the desert.

The climate of Ma'an is cooler than is that of places further south; the thermometer never rises there, it is said, above 40° C. (104° F.). I noted there, at 1 P.M. on June 7th, a temperature of 33° C. (91·4° F.). Unfortunately no meteorological records exist at present for any of the places along the Hedjaz Railway, with the single exception of certain pluviometer readings kept by Meissner Pasha for the last year or two at Ma'an. He has kindly furnished me with the following readings, which show how scanty the rainfall is here:—

Rainfall at Ma'an.

It will be seen from these figures that in two years only some three inches of rain fell at Ma'an. Sand storms, which are very frequent and severe at some places on the line, are not common here; they occur perhaps three or four times in the year.

Ma'an had been suggested as a possible site for the future pilgrims' lazaret. There would be abundance of land suitable for the construction of such lazaret. Good building stone is found in considerable quantity; it occurs in large nummulitic lumps. The station buildings are extensive, and are mostly, if not all, built of this stone. There is a buffet and even an hotel at the station. I had occasion to stop a night

between. Some good may perhaps be done by the application of a pulicide to a room when, for example, a rat is found dead in it and the inhabitants of the room are compelled to live or to work in it. The pulicide must, however, be applied within 24 hours after the death of the rat, and it should be remembered that the room is always liable to reinfection by the advent of fresh plague-infected rats carrying fleas with them into the room. From what has been said above it is obvious that a gaseous disinfectant which is alike poisonous to rats and fleas and which is capable of penetrating into the inaccessible places frequented by these creatures is the only one which offers much hope of success in combating the plague.

Experimental Disinfection.

At present experiments are being carried on in the Bombay Laboratory with a machine (Clayton gas machine) which can produce a large volume of gas, poisonous alike to rats and to fleas. The advantage of this machine is found in a mechanical device which forces the gas into the room to be disinfected and so brings about a greater concentration and diffusion of the disinfectant than have ever before been accomplished. Apart, however, from these experiments, which have not yet been completed, certain experiments have been carried out with liquid disinfectants. These latter experiments prove that the ordinary disinfectants used for destroying bacilli are of little use in destroying plague bacilli which are protected from the action of the disinfectants within the bodies of the fleas which are capable of withstanding immersion without harm in the majority of the most powerful bacteria-killing disinfecting fluids. Thus, for example, Captain Gloster has shown that fleas will emerge unscathed from an exposure of ten minutes in a solution of so powerful a bactericide as a 1 in 500 dilution of acid perchloride of mercury. On the other hand, he has shown that fleas exposed to the action of an emulsion of kerosine oil in a dilution of 1 in 1000 for two minutes are almost always killed, while this substance failed to kill bacteria even in a dilution of 1 in 10. The experiments detailed above were carried out in test tubes, the disinfectants being thus brought intimately in contact with the fleas. It was necessary, therefore, to test the efficiency of these disinfectants in actual plague-infected rooms. On the one hand, the Plague Research Commission has shown that infected rooms still retain their infection after thorough disinfection with so powerful a germicide as 1 in 750 acid perchloride of mercury. Of 31 observations infection remained in the houses after this form of disinfection in 13 cases, or 29 per cent., of the houses examined, a percentage which was almost exactly the same as those found in houses which had not been disinfected at all. On the other hand, Captain Gloster has been able to prove that plague-infected rooms can be readily disinfected by the application of an emulsion of kerosine oil.

Experiments on Animals.

The following further experiments were carried out. A small room or godown was infected with plague. A guinea-pig which had been placed in it was found dead from plague on Feb. 24th. The dead guinea-pig was removed and replaced by a healthy one. This guinea-pig died from plague on Feb. 27th. Another healthy guinea-pig was placed in the godown; it died from plague on March 6th. A fourth guinea-pig was placed in the godown and it died from plague on March 9th. A fifth guinea-pig was then introduced and being sick of plague on the 4th it was chloroformed to death. The godown was thus proved to be thoroughly infected on the 11th. The floor of the godown was washed out with kerosine oil emulsion, 1 in 20, and on the following day a healthy guinea-pig was introduced. This guinea-pig remained healthy and lived in the godown till April 9th. The experiment was repeated in the case of another godown. Three successive guinea-pigs having died from plague in it the godown was then disinfected with 1 in 20 dilution of kerosine oil emulsion. On the following day a healthy guinea-pig was placed in the godown. The guinea-pig lived for days in the godown and remained well in both the above instances. A very badly infected godown was rendered safe by the floor being washed out with a 1 in 20 dilution of kerosine oil emulsion. The majority of the substances tested were patent products and the tests were made with the samples sent for trial.

Kerosine Oil Emulsion Recommended.

Captain Liston strongly recommends the use of kerosine oil emulsion, for disinfection of this sort can with advantage be carried out. The kerosine oil emulsion can be readily prepared. Three parts of Sunlight soap are dissolved by boiling in 15 parts of water. Warmed kerosine oil is added to this soap solution gradually up to 100 parts. The oil and soap water should be mixed together, shaking or stirring the whole. Hydrocarbon emulsion is prepared in a similar way to kerosine oil emulsion, but in this case the hydrocarbon need not be warmed. This substance makes a better emulsion in water than kerosine oil does, and it has a bactericidal power slightly greater than that of carbolic acid, the carbolic acid coefficient being about 20.

THE MUSSEL INDUSTRY AT WELLS: AN INTERESTING STORY IN EPIDEMIOLOGY.

THE city of Norwich has this summer suffered from a considerable amount of enteric fever, which the medical officer of health, Dr. H. Cooper Pattin, suspected to be largely due to the consumption of "shell-fish." In June he communicated with the newly appointed county medical officer of health of Norfolk (Dr. J. T. C. Nash, formerly of Southend, whose work on shell-fish and enteric fever is well known), asking his help administratively in connexion with some cases of this disease which Dr. Pattin thought were due to cockles garnered within the county area. The county medical officer personally inquired into the various cockle-layings mentioned by Dr. Pattin but found the conditions such as to enable him to exonerate these particular layings as probable sources of enteric fever. In the meantime Dr. Pattin had traced the culpable cockles to the Orwell, below Ipswich—a notorious spot—and had added Wells to his list of suspected sources. Dr. Nash promised to visit this latter town in due course.

It appears that there were from Wells two notifications of enteric fever in June and three in July. At the beginning of August Dr. Gordon Calthrop, the medical officer of health of Wells, asked the assistance of the county medical officer of health in tracing the source of this outbreak. His own inquiries had led him to think that the great danger to the town lay in the risk of the spread of the disease through the mussels. Dr. Calthrop further thought that he had been able to exclude water-supplies, milk, insanitary conditions, etc., as probable sources of the outbreak. Dr. Nash accordingly arranged to visit Wells on August 12th and had the advantage of being accompanied on his visit of inspection not only by the medical officer of health (Dr. Calthrop) and the sanitary inspector, but also by the chairman of the sanitary committee of the Wells urban district council. The results of this investigation are quoted fully in the report of the monthly meeting of the Wells urban district council in the Norwich press. Briefly, Dr. Nash's investigation supported Dr. Calthrop's prior conclusions. The pollution of the mussel layings was evidently gross, but Dr. Nash pointed out that Wells being a town with old conservancy methods its sewers carried down very little in the shape of fæcal excrement—which was for the moment a matter for congratulation—because the sewage contaminating the layings was "*pro tanto* less likely to specifically pollute the mussel lays with the specific germ of typhoid fever," but still it was "impossible to take any other view" than that the shell-fish were "liable to serious and occasionally dangerous pollution," seeing that domestic slops containing a considerable quantity of urine (which is known to be infective in from 20 to 30 per cent. of cases of enteric fever), and probably occasionally a little excrement also, were constantly discharging over the mussel layings.

In accordance with Dr. Nash's recommendation Dr. Calthrop sent samples of mussels from the layings to Professor R. T. Hewlett. These were reported by Professor Hewlett as undoubtedly polluted, and he also stated that he had isolated a bacillus which was, so far as his tests went up to the time of writing, indistinguishable from the typhoid bacillus.

It is a curious fact that until the present year Wells has been free from enteric fever for some years, or possibly we should have heard of these layings before now. As Dr. Nash pointed out in his report, "the danger is of course accentuated when typhoid fever exists in the town." After his visit to Wells the county medical officer of health press too far forward they go under this guard and lift it. This action at once stops the machine and the hand cannot be carried forward and crushed. Also only women are employed, and no "young person," therefore it is only natural that there are no accidents on record. If this or any other machine is overloaded there is a fly back switch which at once stops the electric current and it cannot be set on again till the machine is sufficiently unloaded. There is a great advantage in employing electric power to work a laundry. It is very clean and the machinery can be set going any time either night or day, w[illegible] present or absent. It sometimes [illegible] ships with all that they need it [illegible]undry open all night as well as all day. From 55 to 60 laundry workers are employed and the premises are large enough to hold 290 workers without exceeding the limits in regard to space laid down in the Factory Act. [illegible] plenty of breathing room but there [illegible] to pump the air out of the ironing room. On both sides of this vast and lofty department there are high windows with louvre openings at the top and French openings—that is, an opening like a double door—for the lower part of the window. All these are opened in summer, while the openings that are above the heads of the workers are more especially useful in winter. The entire premises are scrubbed out every week and thus all is kept bright and clean. Also many fly-catchers are used, so that the linen shall not be fly-blown or contaminated by these at times dirty insects.

After thus examining the latest improvements affecting the sanitary problem involved in the washing of ship's linen I boarded the *Caronia*. This and her sister ship the *Carmania* represent a new departure in ship building that is of special interest from the health point of view. The only difference between these two ships is that the *Caronia* has reciprocating engines and the *Carmania* has turbine engines. The idea was to try which of the two sorts of engines was the best by applying them to ships that were in every other respect built in the same way, but though these two ships have been running since 1905 it does not seem as if the experiment has as yet supplied an answer to the question. Leaving engineers to decide this matter the point interesting as regards the sanitary aspect of ship building may be stated as follows. To build a high-speed ship—that is, a ship going 16 or more knots per hour—a great deal of room has to be devoted to place large-sized machinery on board, together with the casing of the big funnels and the numerous large ventilators that have to be carried below to supply enough air to the furnaces. All this results in taking up so much space that it has seriously interfered with the size of the cabins. Consequently, from the health point of view, we should advocate slow boats where the machinery does not take up much room, for there would then be a better prospect of plenty of space in the cabins. To-day, however, we have in the *Caronia* and *Carmania* a new type of ship—namely, fast boats with high superstructure. This was obtained by a design and system of balancing which assured an unprecedented stability. In consequence of this stability a large amount of structures could be erected above the main decks or body of the ship. Here, then, was found the means to give large rooms to the passengers in spite of the fact that these are swift ships, for they travel at the average rate of 18 knots an hour; indeed, I have just crossed in the *Caronia* and our average speed was 18·30 knots. The fact is, however, that it was not expected that these ships would travel so fast; they were built for comfort, for freedom from sea-sickness, and not for speed. The rapidity at which they travel has come as an agreeable surprise. From personal experience I can vouch for steadiness. Nevertheless, we had two "moderate gales," a fair allowance of ground swell, and the Atlantic roller came lazily along as usual to try the ship. So steady is this ship that it has become known as the ladies' boat and is patronised by the worst sailors; yet in spite of this fact there were very few people ill during the crossing.

Nowhere have I seen such spacious cabins. The cabin which I occupied, which very rarely holds more than two passengers, though a third bed might be made up on the sofa, measured 10 feet by 12 feet; there are rooms in hotels that are not any larger. There are a large wardrobe in which to hang clothes, a chest of drawers, with a writing-desk that pulls out, and also a folding table that can be placed in any part of the cabin. There are also numerous little shelves and little drawers for holding toilet knick-knacks, &c., and even an arm-chair is provided. This latter certainly was made of light cane work, so that if it should fly about in the cabin during a storm it would not hurt anybody, but the ship is so steady that nothing seems to move. At times I felt inclined to doubt if the ship itself was moving and the ingenious devices which I had brought with me to test motion and vibration had to remain at the bottom of my trunk. This sort of room gives on to the promenade decks. It will be noted that they are called rooms and not cabins, among other reasons because they have windows instead of portholes. Above the window there is a ventilator, which by turning a handle can be opened more or less widely according to the strength of the wind blowing against it, and it is very useful when the wind is too violent to have the window open. Also, if it is very cold the rooms have each a small electric stove and this can be used or not just when required. On the inner side, in the passages there is not only much natural ventilation but air trunks provided with power act as extractors, notably in all the lavatories and bathrooms. If a passenger should close both his window and the ventilator above it there are several openings on the opposite side which he cannot close and he is thus supplied with air in spite of himself. Below, where there are no windows in the third-class and [illegible]w's quarters, the ventilation is assured by powerful fans revolving within thermotanks and patent port-holes that let air in even when they are closed. In all there are 11 machines and they are used sometimes to pump air in and sometimes as extractors. Experiments were made when these ships were constructed and it was found possible to change the entire atmosphere within the ship in four minutes. There is no common department in the steerage, where the passengers sleep side by side; it is divided into compartments with generally only four berths in each.

The stewards' quarters are sometimes satirically denominated the "glory hole." In old ships and some modern ships it is barely fit for human habitation. On the *Caronia* the stewards' quarters are supplied with mechanical ventilation, extensive lavatories, and a bath. My steward, in expatiating to me on these advantages, concluded by saying, "and that is why we stick to the ship." The firemen's quarters I also visited and was pleased to note that they are not allowed to put any food in their lockers, as this is a dirty and dangerous practice which attracts rats and other vermin. Of course, there was the usual prevalence of coal dust, though their quarters are constantly scrubbed out. Descending into the engine room the sense of size and power is quite overwhelming, but when looking over the details of the machinery there also comes the impression of the fallibility of man and the modesty of engineers. Whether it was a simple water gauge or a complex piece of machinery I had hardly been explained its purpose than I was shown a duplicate or some other contrivance that would do the work as well if what was actually in use broke down. Naturally, this adds greatly to the security of travel. Then again, and even if we struck a rock and had a big hole knocked into the bottom of the ship, there is another bottom at a higher level that would in all probability escape injury and prevent the water penetrating to the interior of the ship. Of course, there are also the automatic bulkheads that can isolate an injured section of the ship from all the rest of the structure. Reaching finally the much-dreaded coal-hole, where the stokers pile the fuel into the furnaces, I found the heat not so great as when visiting other parts of the machinery. There is here also probably more fresh air than in any other part of the ship. This must be the case, if not for the sake of the men, then for the coals that could not burn but for an ample supply of oxygen. Undoubtedly, stoking is hot work, requires great muscular effort, and should only be attempted by men of strong constitution, and the hours of labour must be short. But it is a great advantage for the firemen of the *Caronia* to possess ample space and unlimited hot and cold water to wash themselves with after they have done their work. It was a pleasure for me to watch several of them evidently enjoying a good splash. Thus it may be said that both for the crew and for the passengers this ship affords a great measure of comfort, of space, and of air, and consequently provides the essential conditions for insuring good health to all on board. Nor can I quit this subject without

between. Some good may perhaps be done by the application of a pulicide to a room when, for example, a rat is found dead in it and the inhabitants of the room are compelled to live or to work in it. The pulicide must, however, be applied within 24 hours after the death of the rat, and it should be remembered that the room is always liable to reinfection by the advent of fresh plague-infected rats carrying fleas with them into the room. From what has been said above it is obvious that a gaseous disinfectant which is alike poisonous to rats and fleas and which is capable of penetrating into the inaccessible places frequented by these creatures is the only one which offers much hope of success in combating the plague.

Experimental Disinfection.

At present experiments are being carried on in the Bombay Laboratory with a machine (Clayton gas machine) which can produce a large volume of gas, poisonous alike to rats and to fleas. The advantage of this machine is found in a mechanical device which forces the gas into the room to be disinfected and so brings about a greater concentration and diffusion of the disinfectant than have ever before been accomplished. Apart, however, from these experiments, which have not yet been completed, certain experiments have been carried out with liquid disinfectants. These latter experiments prove that the ordinary disinfectants used for destroying bacilli are of little use in destroying plague bacilli which are protected from the action of the disinfectants within the bodies of the fleas which are capable of withstanding immersion without harm in the majority of the most powerful bacteria-killing disinfecting fluids. Thus, for example, Captain Gloster has shown that fleas will emerge unscathed from an exposure of ten minutes in a solution of so powerful a bactericide as a 1 in 500 dilution of acid perchloride of mercury. On the other hand, he has shown that fleas exposed to the action of an emulsion of kerosine oil in a dilution of 1 in 1000 for two minutes are almost always killed, while this substance failed to kill bacteria even in a dilution of 1 in 10. The experiments detailed above were carried out in test tubes, the disinfectants being thus brought intimately in contact with the fleas. This guinea-pig remained healthy and lived in the godown till April 9th. The experiment was repeated in the case of another godown. Three successive guinea-pigs having died from plague in it the godown was then disinfected with 1 in 20 dilution of kerosine oil emulsion. On the following day a healthy guinea-pig was placed in the godown. The guinea-pig lived for days in the godown and remained well in both the above instances. A very badly infected godown was rendered safe by the floor being washed out with a 1 in 20 dilution of kerosine oil emulsion. The majority of the substances tested were patent products and the tests were made with the samples sent for trial.

Kerosine Oil Emulsion Recommended.

Captain Liston strongly recommends the use of kerosine oil emulsion, for disinfection of this sort can with advantage be carried out. The kerosine oil emulsion can be readily prepared. Three parts of Sunlight soap are dissolved by boiling in 15 parts of water. Warmed kerosine oil is added to this soap solution gradually up to 100 parts. The oil and soap water should be mixed together, shaking or stirring the whole. Hydrocarbon emulsion is prepared in a similar way to kerosine oil emulsion, but in this case the hydrocarbon need not be warmed. This substance makes a better emulsion in water than kerosine oil does, and it has a bactericidal power slightly greater than that of carbolic acid, the carbolic acid coefficient being about 20.

THE MUSSEL INDUSTRY AT WELLS: AN INTERESTING STORY IN EPIDEMIOLOGY.

THE city of Norwich has this summer suffered from a considerable amount of enteric fever, which the medical officer of health, Dr. H. Cooper Pattin, suspected to be largely due to the consumption of "shell-fish." In June he communicated with the newly appointed county medical officer of health of Norfolk (Dr. J. T. C. Nash, formerly of Southend, whose work on shell-fish and enteric fever is well known), asking his help administratively in connexion with some cases of this disease which Dr. Pattin thought were due to cockles garnered within the county area. The county medical officer personally inquired into the various cockle-layings mentioned by Dr. Pattin but found the conditions such as to enable him to exonerate these particular layings as probable sources of enteric fever. In the meantime Dr. Pattin had traced the culpable cockles to the Orwell, below Ipswich—a notorious spot—and had added Wells to his list of suspected sources. Dr. Nash promised to visit this latter town in due course.

It appears that there were from Wells two notifications of enteric fever in June and three in July. At the beginning of August Dr. Gordon Calthrop, the medical officer of health of Wells, asked the assistance of the county medical officer of health in tracing the source of this outbreak. His own inquiries had led him to think that the great danger to the town lay in the risk of the spread of the disease through the mussels. Dr. Calthrop further thought that he had been able to exclude water-supplies, milk, insanitary conditions, etc., as probable sources of the outbreak. Dr. Nash accordingly arranged to visit Wells on August 12th and had the advantage of being accompanied on his visit of inspection not only by the medical officer of health (Dr. Calthrop) and the sanitary inspector, but also by the chairman of the sanitary committee of the Wells urban district council. The results of this investigation are quoted fully in the report of the monthly meeting of the Wells urban district council in the Norwich press. Briefly, Dr. Nash's investigation supported Dr. Calthrop's prior conclusions. The pollution of the mussel layings was evidently gross, but Dr. Nash pointed out that Wells being a town with old conservancy methods its sewers carried down very little in the shape of fæcal excrement—which was for the moment a matter for congratulation—because the sewage contaminating the layings was "*pro tanto* less likely to specifically pollute the mussel lays with the specific germ of typhoid fever," but still it was "impossible to take any other view" than that the shell-fish were "liable to serious and occasionally dangerous pollution," seeing that domestic slops containing a considerable quantity of urine (which is known to be infective in from 20 to 30 per cent. of cases of enteric fever), and probably occasionally a little excrement also, were constantly discharging over the mussel layings.

In accordance with Dr. Nash's recommendation Dr. Calthrop sent samples of mussels from the layings to Professor R. T. Hewlett. These were reported by Professor Hewlett as undoubtedly polluted, and he also stated that he had isolated a bacillus which was, so far as his tests went up to the time of writing, indistinguishable from the typhoid bacillus.

It is a curious fact that until the present year Wells has been free from enteric fever for some years, or possibly we should have heard of these layings before now. As Dr. Nash pointed out in his report, "the danger is of course accentuated when typhoid fever exists in the town." After his visit to Wells the county medical officer of health attend any patient who lives beyond two miles from his residence. It is suggested provisionally that 70 per cent. of the application fees and subscriptions shall be divided amongst the members of the medical staff, that 20 per cent. shall be paid to the general dispensary to cover the cost of drugs, dressings, &c., and that the remaining 10 per cent. shall be allotted to the secretary to cover the cost of his services, staff, office, &c. It is a far better scheme than that which was put forward about a year ago by the General Medical Practitioners' Union and the central division of the British Medical Association, and which was subjected to such severe criticism that it was abandoned. It has already aroused great interest, and although it is obvious that it will not satisfy everyone there is no doubt it will receive careful consideration when it is submitted to the annual meeting of the General Medical Practitioners' Union.

The Women's Hospital.

The need for an increased income if the Women's Hospital is to continue and to extend its useful work has led to the formation of a Women's Hospital League the object of which is to raise £1000 per annum for the Birmingham and Midland Hospital for Women, and when this object has been attained to give assistance to other hospitals of the city. The necessity of the Women's Hospital is urgent and there are plenty of people who can afford to give it support, but the difficulty is to induce them to give money. Mr. Neville Chamberlain, who moved that the league should be formed, was undoubtedly correct when he stated that there were many people in Birmingham who had learned how to make money but who had not yet learned how to spend it. It is quite possible that women may be more efficient instructors in the latter art than men, and it is suggested that each district and subdistrict of the city should have its divisional committee and officers. If the scheme is carried out on these lines and energy is thrown into it success seems certain.

The Health of the City.

Now that the most trying period of the summer is over it is interesting to note the gradual rise and fall of the death-rate and its association with the increase and decline of diarrhœa. The death-rate for the week ending July 11th was 11·7 per 1000, and in the published report there was no particular mention of diarrhœa. By the end of the following week the death-rate had risen to 13·3 per 1000 and there had been 11 deaths from diarrhœa. During the week ending August 1st the death-rate fell to 12·1 per 1000 and the deaths from diarrhœa were 14. The following week the death-rate rose to 13·8 per 1000 and the deaths from diarrhœa to 25. The rise continued during the next two weeks and in the week ending August 22nd the death-rate reached 20·1 per 1000 and the deaths from diarrhœa were 69. By August 29th the death-rate had fallen to 17·9 per 1000 and the deaths from diarrhœa to 52. By Sept. 12th the death-rate had reached 13·9 per 1000 and the deaths from diarrhœa were reduced to 24, and during the week ending Sept. 18th the death-rate was 14·1 per 1000 and the deaths from diarrhœa numbered 17.

The Prevalence of Scarlet Fever and Diphtheria.

THE medical officer of health reported at the meeting of the health committee held on Sept. 17th that 117 cases of scarlet fever were notified during the week ended Sept. 12th, compared with 86 in the previous week; and 28 cases of diphtheria, against 13 in the previous week. There are at present 687 patients under treatment in the city hospitals for scarlet fever and 59 for diphtheria.

Bootle and the Provision for Small-pox.

The scheme of the Bootle corporation to erect a small-pox hospital on the boundary of Maghull, Lydiate, and Aughton has met with opposition by the West Lancashire rural council. The scheme includes the provision of 20 beds, medical man's house, nurses' administrative block, and other accessory buildings; to put down concrete foundations for a building providing another 20 beds and an observation pavilion containing four beds; and to provide for the treatment of the sewage from the institutions. Altogether the land that Bootle proposes to acquire amounts to about 16 acres. The Bootle corporation has already a small-pox and general infectious diseases hospital in the borough itself, but the Local Government Board will not sanction the borrowing of money for a further enlargement until the small-pox cases have been removed from their present position. The rural council at its recent meeting unanimously resolved to oppose the proposal of the Bootle corporation and appointed five members of the council as a subcommittee to deal with the matter and to arrange for representation at the inquiry by the Local Government Board to be held at Bootle to-day.

Royal Hospital for Sick Children, Glasgow.

ABOUT a year ago the directors of the Sick Children's Hospital in Glasgow issued an appeal for £100,000 to purchase a site and to rebuild the hospital and to extend the existing branch in the country. This important movement was rendered necessary by the fact that the premises in Garnethill, which had been converted into a hospital with 74 beds a quarter of a century ago, were utterly inadequate to meet the increasing and urgent demands for admission. The hospital itself also in many essential respects fell far short of modern requirements. When the rebuilding fund amounted to £50,000 the directors, being assured that the necessary funds would be provided, felt justified in proceeding with the selection of a site which would comply with the various requirements specified in the appeal. After careful inquiry and consultation with experts and the leading medical and surgical authorities, a square of ten acres has been secured on the best and highest parts of the estate of Yorkhill. The site is the best that could be obtained in the city in respect of its exposure, openness, and elevation. It is accessible from all parts of the city by rail, tramway, and ferry, and is in close proximity to the University. It is proposed to proceed with the new hospital at once, the intention being to erect a building with accommodation for 200 beds in the meantime, leaving ample room for extension in the future as occasion requires. It is intended that the hospital shall be constructed as simply and cheaply as possible, consistent with the greatest efficiency. Up to the present subscriptions have been received to the amount of £68,000. In the existing hospital over 1000 children, all under 12 years of age, are treated annually in the 74 cots and over 11,000 are treated at the dispensary. Further, there are always on the books awaiting admission, often for considerable periods, from 150 to 200 cases, many of which are urgent.

Govan Lunacy Board.

The new pavilions which have been erected by the Govan parish lunacy board at Hawkhead Asylum were formally opened last week. The necessity for the erection of these additions was caused by want of accommodation, especially on the male side. The new pavilions will provide special accommodation for aged and infirm patients up to the number of 120. Additional accommodation has also been provided for 40 attendants. The cost of the new buildings and furnishings is £25,884, which works out at something like £154 per head. The institution now affords accommodation for 688 patients and the grounds attached to it extend to 340 acres.

The Glasgow Cancer and Skin Institution.

This institution continues to wage war against the surgical treatment of cancer. At the annual meeting the chairman, who is a layman, referred in his speech to the cases of cancer treated during the year. Apart from the continued cases, there were, he said, 65 new patients, 55 of whom were turned out well and were no more heard of, so that, according to the chairman, there was no recurrence of the malady in any of these cases. In most cases there had been one, two, or more surgical operations before they came to the institution, where the cancer was eliminated by medical treatment. Dealing with the details of certain cases, in one instance the cancer arose in the cheek of a fireman from a spark from a locomotive engine. The man was restored to health. The chairman went on to say that cases like that should convince

between. Some good may perhaps be done by the application of a pulicide to a room when, for example, a rat is found dead in it and the inhabitants of the room are compelled to live or to work in it. The pulicide must, however, be applied within 24 hours after the death of the rat, and it should be remembered that the room is always liable to reinfection by the advent of fresh plague-infected rats carrying fleas with them into the room. From what has been said above it is obvious that a gaseous disinfectant which is alike poisonous to rats and fleas and which is capable of penetrating into the inaccessible places frequented by these creatures is the only one which offers much hope of success in combating the plague.

Experiments with Disinfectants.

At present experiments are being carried on in the Bombay Laboratory with a machine (Clayton gas machine) which can produce a large volume of gas poisonous alike to rats and to fleas. The advantage of this machine is found in a mechanical device which forces the gas into the room to be disinfected and so brings about a greater concentration and diffusion of the disinfectant than have ever before been accomplished. Apart, however, from these experiments, which have not yet been completed, certain experiments have been carried out with liquid disinfectants. These latter experiments prove that the ordinary disinfectants used for destroying bacilli are of little use in destroying plague bacilli which are protected from the action of the disinfectants within the bodies of the fleas which are capable of withstanding immersion without harm in the majority of the most powerful bacteria-killing disinfecting fluids. Thus, for example, Captain Gloster has shown that fleas will emerge unscathed from an exposure of ten minutes in a solution of so powerful a bactericide as a 1 in 500 dilution of acid perchloride of mercury. On the other hand, he has shown that fleas exposed to the action of an emulsion of kerosene oil in a dilution of 1 in 1000 for two minutes are almost always killed, while this substance failed to kill bacilli even in a dilution of 1 in 10. The experiments detailed above were carried out in test tubes, the disinfectants being thus brought intimately in contact with the fleas. It was necessary, therefore, to test the efficiency of these disinfectants in actual plague-infected rooms. On the one hand, the Plague Research Commission has shown that infected rooms still retain their infection after thorough disinfection with so powerful a germicide as 1 in 750 acid perchloride of mercury. Of 31 observations infection remained in the houses after this form of disinfection in 13 cases, or 29 per cent., of the houses examined, a percentage which was almost exactly the same as those found in houses which had not been disinfected at all. On the other hand, Captain Gloster has been able to prove that plague-infected rooms can be readily disinfected by the application of an emulsion of kerosene oil.

Experiments on Animals.

The following further experiments were carried out. A small room or godown was infected with plague. A guinea-pig which had been placed in it was found dead from plague on Feb. 24th. The dead guinea-pig was removed and replaced by a healthy one. This guinea-pig died from plague on Feb. 27th. Another healthy guinea-pig was placed in the godown; it died from plague on March 5th. A fourth guinea-pig was placed in the godown and it died from plague on March 9th. A fifth guinea-pig was then introduced and [illegible] formed to [illegible]. The godown was thus proved to be thoroughly infected on the 11th. The floor of the godown was washed out with kerosene oil emulsion, 1 in 20, and on the following day a healthy guinea-pig was introduced. This guinea-pig remained healthy and lived in the godown till April 9th. The experiment was repeated in the case of another godown. Three successive guinea-pigs having died from plague in it the godown was then disinfected with a 1 in 20 dilution of kerosene oil emulsion. On the following day a healthy guinea-pig was placed in the godown. This guinea-pig lived for days in the godown and remained well. In both the above instances a very badly infected godown was rendered safe by the floor being washed out with a 1 in 20 dilution of kerosene oil emulsion. [illegible] substances tested were patent products and the tests were made with the samples sent for trial.

Kerosene Oil Emulsion Recommended.

Captain Liston strongly recommends the use of kerosene oil emulsion, for disinfection of this sort can with advantage be carried out. The kerosene oil emulsion can be readily prepared. Three parts of Sunlight soap are dissolved by boiling in 15 parts of water. Warmed kerosene oil is added to this soap solution gradually up to 100 parts. The oil and soap water should be mixed together, shaking or stirring the while. Hydrocarbon emulsion is prepared in a similar way to kerosene oil emulsion, but in this case the hydrocarbon need not be warmed. This substance makes a better emulsion in water than kerosene oil does, and it has a bactericidal power slightly greater than that of carbolic acid, the carbolic acid coefficient being about 20.

THE MUSSEL INDUSTRY AT WELLS: AN INTERESTING STORY IN EPIDEMIOLOGY.

The city of Norwich has this summer suffered from a considerable amount of enteric fever, which the medical officer of health, Dr. H. Cooper Pattin, suspected to be largely due to the consumption of "shell-fish." In June he communicated with the newly appointed county medical officer of health of Norfolk, Dr. J. E. C. Nash, formerly of [illegible]

Royal Hospital for Sick Children, Glasgow.

ABOUT a year ago the directors of the Sick Children's Hospital in Glasgow issued an appeal for £100,000 to purchase a site and to rebuild the hospital and to extend the existing branch in the country. This important movement was rendered necessary by the fact that the premises in Garnethill, which had been converted into a hospital with 74 beds a quarter of a century ago, were utterly inadequate to meet the increasing and urgent demands for admission. The hospital itself also in many essential respects fell far short of modern requirements. When the rebuilding fund amounted to £50,000 the directors, being assured that the necessary funds would be provided, felt justified in proceeding with the selection of a site which would comply with the various requirements specified in the appeal. After careful inquiry and consultation with experts and the leading medical and surgical authorities, a square of ten acres has been secured on the best and highest parts of the estate of Yorkhill. The site is the best that could be obtained in the city in respect of its exposure, openness, and elevation. It is accessible from all parts of the city by rail, tramway, and ferry, and is in close proximity to the University. It is proposed to proceed with the new hospital at once, the intention being to erect a building with accommodation for 200 beds in the meantime, leaving ample room for extension in the future as occasion requires. It is intended that the hospital shall be constructed as simply and cheaply as possible, consistent with the greatest efficiency. Up to the present subscriptions have been received to the amount of £68,000. In the existing hospital over 1000 children, all under 12 years of age, are treated annually in the 74 cots and over 11,000 are treated at the dispensary. Further, there are always on the books awaiting admission, often for considerable periods, from 150 to 200 cases, many of which are urgent.

Govan Lunacy Board.

The new pavilions which have been erected by the Govan parish lunacy board at Hawkhead Asylum were formally opened last week. The necessity for the erection of these additions was caused by want of accommodation, especially on the male side. The new pavilions will provide special accommodation for aged and infirm patients up to the number of 120. Additional accommodation has also been provided for 40 attendants. The cost of the new buildings and furnishings is £25,884, which works out at something like £154 per head. The institution now affords accommodation for 688 patients and the grounds attached to it extend to 340 acres.

The Glasgow Cancer and Skin Institution.

This institution continues to wage war against the surgical treatment of cancer. At the annual meeting the chairman, who is a layman, referred in his speech to the cases of cancer treated during the year. Apart from the continued cases, there were, he said, 65 new patients, 55 of whom were turned out well and were no more heard of, so that, according to the chairman, there was no recurrence of the malady in any of these cases. In most cases there had been one, two, or more surgical operations before they came to the institution, where the cancer was eliminated by medical treatment. Dealing with the details of certain cases, in one instance the cancer arose in the cheek of a fireman from a spark from a locomotive engine. The man was restored to health. The chairman went on to say that cases like that should convince the inoculation procedure and as to the reasons why no good results have accrued therefrom. We imagine that it would be difficult to procure trustworthy statistics as regards the fatality rate of inoculated small-pox, but it would be instructive could some data be given as well as information relative to the spread or non-spread of small-pox through inoculation. Dr. Stanley adopts apparently as his standard of successful vaccination repetition of the process until it no longer takes, or, rather, he states that vaccination repeated until it no longer takes always prevents small-pox and he expresses the opinion that there is so much small-pox in Shanghai that vaccination should be repeated until it no longer takes. He thinks that, as the Chinese practised inoculation of mild small-pox as a protection against severe small-pox long before the days of Jenner, vaccination will be readily embraced by them. As many as 1418 vaccinations among Chinese and indigent foreigners were carried out during the year. There were 18 deaths from cholera amongst foreigners and 655 among Chinese, and Dr. Stanley appears to consider that infected food is a very common source of the disease and that a common agency through which the food is infected is the fly. There were 57 cases of enteric fever among the foreigners and it is thought that the method of growing oysters near Ningpo for the Shanghai market may be responsible for some of the disease if the oysters are eaten raw. It is a matter of interest in connexion with the geographical distribution of Malta fever to note that two deaths certified as due to this disease occurred in Shanghai during 1907, and it seems probable that some of the cases certified as being enteric fever are cases of Malta fever. We are not told whether there are goats used as sources of milk in Shanghai and, if so, to what variety of goats they belong. We have still much to learn as to the distribution and etiology of Malta fever. Among the useful duties performed by the municipal laboratory is the examination of mosquitoes for each of the eight sanitary districts and the discovery of yellow fever bearing mosquitoes is a matter of importance in relation to the prospective opening of the Panama Canal, as it is conceivable that the Shanghai mosquitoes may become the carriers of yellow fever. Probably, however, the work now being carried out by the Americans between Panama and Colon in the clearance of swamp and undergrowth will reduce these risks to a minimum. There are occasionally rabid dogs in Shanghai, notwithstanding the muzzling order and the licensing of dogs, and the virus of the Shanghai disease seems more virulent than that of Europe, the incubation period being shorter. Among the prisoners in the Souza prison there was in 1907 an outbreak of relapsing fever, there being 43 cases and two deaths. There was also cattle plague amongst cattle in the dairies. Shanghai has its municipal abattoir, but during the year 1907 no animal was rejected on account of tuberculosis, evidence, Dr. Stanley thinks, of the extreme rarity of bovine tuberculosis among the local cattle. Good meat is stamped "Killed in municipal slaughter-house," and no meat is allowed to be sold from any shop or taken into the settlement unless it bears a municipal stamp. Meat inferior in quality but free from disease is passed for sale on stalls only and marked "second quality." Would that English towns would follow this Shanghai example.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN 76 of the largest English towns 8144 births and 4337 deaths were registered during the week ending Sept. 19th. The annual rate of mortality in these towns, which had steadily declined from 15·8 to 14·2 per 1000 in the four preceding weeks, further fell to 13·9 during the week under notice. During the first 12 weeks of the current quarter the annual death-rate in these towns averaged 13·4 per 1000, and in London the mean rate in the same period did not exceed 12·5. The lowest annual death-rates in these 76 towns during the week under notice were 3·7 in Bournemouth, 4·5 in West Bromwich, 6·7 in Hornsey, and 6·9 in East Ham; the rates in the other towns ranged upwards, however, to 19·6 in Grimsby and in Merthyr Tydfil, 20·9 in Wigan, 21·9 in Stockport, and 23·5 in Great Yarmouth. In London the death-rate during the week was 13·9 per 1000. The 4337 deaths from all causes in the 76 towns showed a further decline of 96 from the decreasing numbers in recent weeks, and included 677 which were referred to the principal epidemic diseases, against 1343, 1067, and 840 in the three preceding weeks; of these 677 deaths, 507 resulted from diarrhœa, 43 from diphtheria, 38 from whooping-cough, 36 from measles, 28 from scarlet fever, and 25 from "fever" (principally enteric), but not one from small-pox. The deaths referred to these epidemic diseases during the week were equal to an annual rate of 2·2 per 1000, against 4·3, 3·4, and 2·7 in the three preceding weeks; in London the death-rate from these diseases did not exceed 2·1. No death from any of these epidemic diseases was registered last week in Bournemouth or in Hastings, whereas the annual death-rates therefrom ranged upwards in the other large towns to 5·3 per 1000 in Rochdale, 5·6 in St. Helens, 6·2 in Hull, and 7·6 in Stockport. The deaths attributed to diarrhœa in the 76 towns, which had declined in the four preceding weeks fr[illegible] to 668, further fell to 507 in the week under notice[illegible] highest death-rates last week from this cause were 4·6 [illegible] Birkenhead, 5·0 in St. Helens, 5·2 in Hull, and 6·6 in Stockport. The 43 deaths referred to diphtheria showed a further increase upon recent weekly numbers, and caused the highest death-rates, 1·2 in Derby and 1·3 in Reading. The 38 fatal cases of whooping-cough showed a marked decline, and were fewer than in any previous week of this year. The 36 deaths from measles somewhat exceeded the low number in the previous week; this disease caused a death-rate last week equal to 1·2 in Rochdale and to 1·6 in Oldham. The 28 fatal cases of scarlet fever included nine in London and its suburban districts, three in Birmingham and King's Norton, eight in Liverpool and Bootle, and three in Manchester and Salford. The 25 deaths referred to "fever" showed a decline of nine from the number in the previous week; the two fatal cases in Wigan were equal to an annual rate of 1·2 per 1000. The number of scarlet fever patients under treatment in the Metropolitan Asylums and the London Fever Hospitals, which had been 2855 and 3005 in the two preceding weeks, had further risen to 3285 on Sept. 19th; the number of new cases of this disease admitted to these hospitals during the week under notice were 625, against 377, 395, and 472 in the three previous weeks. The deaths in London referred to pneumonia and other diseases of the respiratory organs, which had been 102 and 124 in the two preceding weeks, further rose to 137 last week, but were nine below the corrected average number in the corresponding week of the five years 1903-07. The causes of 42, or 1·0 per cent., of the deaths registered in the 76 towns last week were not certified either by a registered medical practitioner or by a coroner. All the causes of death were again duly certified in Manchester, Leeds, Bristol, West Ham, Bradford, Newcastle-on-Tyne, Leicester, and in 47 other smaller towns during the week under notice; eight uncertified causes of death were, however, registered during the week in Birmingham, six in Liverpool, four in Sheffield, three in Preston, and two in South Shields.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in eight of the principal Scotch towns, which had been equal to 15·4, 14·8, and 13·7 per 1000 in the three preceding weeks, rose again to 14·4 in the week ending Sept. 19th. During the first 12 weeks of the current quarter the annual death-rate in these eight towns averaged 13·8 per 1000 and exceeded by 0·4 the mean rate during the same period in the 76 English towns. Among the eight Scotch towns the death-rate during the week under notice ranged from 7·4 and 10·0 in Perth and Aberdeen to 16·1 in Dundee and 16·6 in Glasgow. The 503 deaths in the eight towns showed an increase of 24 upon the low number in the previous week, and included 65 which were referred to the principal epidemic diseases, against numbers declining from 107 to 87 in the four preceding weeks; of these 65 deaths, 35 resulted from diarrhœa, ten from whooping-cough, nine from "fever," seven from diphtheria, and two each from measles and scarlet fever, but not one from small-pox. These 65 deaths were equal to an annual rate of 1·8 per 1000, which was 0·4 below the mean rate from the same diseases in the 76 large English towns. The deaths attributed to diarrhœa in the eight Scotch towns, whic had ranged from 63 to 52 in the four preceding w been only nine mild cases during the year. Tuberculosis has also much lessened owing to abundance of fresh air, liberal diet, personal cleanliness, and as far as possible isolation of advanced cases. Financially, the net average cost of each patient (deducting repayment of loans, receipts from paying patients, &c.) was £22 11*s.* 5*d.* (the average for all Irish asylums under the same head for the last recorded year was £23 3*s.* 4*d.*). The actual net cost of maintenance paid directly from the county rates (deducting Treasury grant, &c.) averages about £8 0*s.* 3*d.* per head. A new scheme of sewage disposal (bacteria tanks and "spray" filter of Adams type) has been completed. A new water-supply (supplementary or alternative) is in process of being got ready. Mr. M. J. Nolan's report is most interesting.

Double Tenement Houses, Belfast.

Scandalous revelations have come out at the revision courts with regard to the evils of the double tenement system of houses, and the offence in such conditions not only against sanitary principles but morality which is involved. Dr. Todd, K.C., on Sept. 21st, at a meeting of the revision courts, characterised the state of matters as disgraceful, and Mr. Fleming, K.C. (another of the revising barristers), said it was contrary to all morality and decency for agents of landlords to make an arrangement by which the tenant of the upper half of the house had to go through the kitchen in order to get to the yard. The Belfast Health Association condemned very strongly such double tenement houses.

The New Public Abattoir in Belfast.

That a new abattoir in Belfast is an absolute necessity is clear and the Public Health Commission recommends that the corporation should, at the earliest possible moment, take steps to provide a more modern and commodious abattoir on a more suitable site. The matter has been under discussion since Dec. 1st, 1897, and at a meeting of the market committee held on Sept. 5th last the following motion (proposed by Dr. H. O'Neill) was carried by 8 to 2:—

> That in view of the necessity for additional and improved abattoir accommodation for the city and the expression of opinion by the Local Government Board in their letter of July 25th last to the effect that the selection of a suitable site for, and the erect
> date abattoir, for which a loan of £30,000 was
> eight years ago, is a matter which should recei
> tion of the corporation, this committee strongly recommend the council to authorise the erection of a new abattoir on the Stewart-street site, at an estimated cost of £32,118, in accordance with plans prepared by the city surveyor.

An amendment to authorise the erection of extended abattoir accommodation on the present site was lost. On the other hand, a committee of experts appointed by the corporation, consisting of the president of the Ulster Medical Society (Dr. J. McCaw), the Local Government Board inspector (Dr. C. J. Clibborn), and Mr. H. W. Bailie (superintendent medical officer of health of Belfast), has reported adversely on both sites. The Master Butchers' Federation of Belfast has recommended another site as suitable for the abattoir—that is, the present horse market site—and it condemns the present site, while the city surveyor of Belfast approves of the horse fair site, except as to cost and interference with the convenience of the markets, as the best for abattoir purposes from every point of view. It is clear that the present site is the worst and the council will have to decide which of the other two is the better, as the market committee has failed to get other available sites. The matter will come up for discussion again on Oct. 1st, when it is hoped that a final decision will be arrived at.

Sept. 22nd.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

The Action of Human Serum upon Trypanosoma Pecaudi.

ON August 24th M. Thiroux and M. d'Anfreville made a communication to the Academy of Sciences. Following on long and minute researches they are able to announce that human blood serum has an effect upon trypanosoma Pecaudi which is demonstrably preventive and curative, similar to the effect which it has upon trypanosoma Brucei, trypanosoma Evansi, and trypanosoma equinum. They have also determined that this action of human serum takes a long time in becoming exhausted. The serum of patients suffering from sleeping sickness, which M. Thiroux has lately demonstrated to be prophylactic against trypanosoma Gambiense, influences trypanosoma Pecaudi in the same manner as does normal human serum. But as the latter substance has no influence upon trypanosoma Gambiense it is reasonable to agree with these two distinguished authors that in spite of certain morphological resemblances trypanosoma Pecaudi and trypanosoma Gambiense form two distinct species.

The Eighth International Congress of Hydrology, Climatology, Geology, and Physical Therapeutics.

This congress will be held at Algiers in the Easter holidays of next year, from April 4th to 10th. The subscription for full members is 20 francs and for associate members 10 francs. Either membership entitles its holder to the customary reduced charges at hotels and restaurants and on railways and boats, and admits to the various fêtes and entertainments. Excursions across Tunis and Algeria will be made, comprising visits to interesting towns. A ladies committee is to be organised to receive and to look after the ladies who attend. For full particulars application should be made to M. Raynaud, 7, Place de la République, Algiers. A number of papers and reports have already been promised. Anyone desirous of contributing a paper or note should submit them by Jan. 31st, 1909, at the latest.

A Hospital Tragedy.

A patient at the Pitié Hospital, after showing signs of insanity, recently took advantage of the drowsiness of a night attendant to attack him with a knife. After stabbing him several times he turned the knife on himself and then jumped out of the window, which was high above the ground. The madman is dead and the attendant is wounded dangerously.

A Medical Trip to London.

The President of the British Balneological and Climatological Society has written to the secretary of the Paris Medical Hydrological Society to say that, as it is probable that some of the French society's members will be visiting London before the Exhibition closes, in the name of the British society he invites them and all other French medical men to a meeting of his society on Oct. 29th. The committee of the Paris Hydrological Society finds that a large number will accept this courteous invitation and takes great pleasure in furthering the project of this trip to London, which is being organised by Dr. Leonard Williams, editor of the *Journal of Balneology and Climatology.*

Precautions against Cholera.

The official announcement of the existence of cholera in Russia and the news of its rapid progress are beginning to cause some disquietude among the population of Paris. The Minister of the Interior has summoned an extraordinary meeting of the Permanent Consultative Committee of the Public Health and this committee has decided to set in action from the present time the sanitary defence service, both in the seaports and on the land frontier (*service à deux échelons*) for travellers arriving in France from Russia. A Ministerial decree in conformity with this resolution of the committee has been issued containing the following regulations. Every ship arriving at a French port from the Baltic or the Black Sea will have to show a clean bill of health before admission to free *pratique* or will have to stay in quarantine for five days. At all the land frontiers there are posts for medical inspection. Every traveller on his way from Russia will be medically examined, and all those who are found to be ill or any suspect will be immediately drafted into hospital, where their clothing and luggage will be disinfected by stoving. They will be kept in hospital until they are cured. Every traveller who is not detained at the frontier will receive a bill of health and will have to declare the address to which he is travelling. The mayor of this place will be advised by telegraph of his arrival and the traveller will have to present himself before that official who will order him to be examined by a medical man and kept under observation during five days. If he should show symptoms of cholera during this period he will be isolated until he is well. If he leaves the place during this period of five days he will have again to declare his destination in order that he may undergo a similar observation when he arrives there. Every hotel-keeper who lodges a traveller coming from the infected areas must declare the same within 24 hours to the mayor of his commune or to the prefect of police if he lives in Paris. Every medical the inoculation procedure and as to the reasons why no good results have accrued therefrom. We imagine that it would be difficult to procure trustworthy statistics as regards the fatality rate of inoculated small-pox, but it would be instructive could some data be given as well as information relative to the spread or non-spread of small-pox through inoculation. Dr. Stanley adopts apparently as his standard of successful vaccination repetition of the process until it no longer takes, or, rather, he states that vaccination repeated until it no longer takes always prevents small-pox, and he expresses the opinion that there is so much small-pox in Shanghai that vaccination should be repeated until it no longer takes. He thinks that, as the Chinese practised inoculation of mild small-pox as a protection against severe small-pox long before the days of Jenner, vaccination will be readily embraced by them. As many as 1418 vaccinations among Chinese and indigent foreigners were carried out during the year. There were 18 deaths from cholera amongst foreigners and 655 among Chinese, and Dr. Stanley appears to consider that infected food is a very common source of the disease and that a common agency through which the food is infected is the fly. There were 57 cases of enteric fever among the foreigners and it is thought that the method of growing oysters near Ningpo for the Shanghai market may be responsible for some of the disease if the oysters are eaten raw. It is a matter of interest in connexion with the geographical distribution of Malta fever to note that two deaths certified as due to this disease occurred in Shanghai during 1907, and it seems probable that some of the cases certified as being enteric fever are cases of Malta fever. We are not told whether there are goats used as sources of milk in Shanghai and, if so, to what variety of goats they belong. We have still much to learn as to the distribution and etiology of Malta fever. Among the useful duties performed by the municipal laboratory is the examination of mosquitoes for each of the eight sanitary districts and the discovery of yellow fever bearing mosquitoes is a matter of importance in relation to the prospective opening of the Panama Canal, as it is conceivable that the Shanghai mosquitoes may become the carriers of yellow fever. Probably, however, the work now being carried out by the Americans between Panama and Colon in the clearance of swamp and undergrowth will reduce these risks to a minimum. There are occasionally rabid dogs in Shanghai, notwithstanding the muzzling order and the licensing of dogs, and the virus of the Shanghai disease seems more virulent than that of Europe, the incubation period being shorter. Among the prisoners in the Souza prison there was in 1907 an outbreak of relapsing fever, there being 43 cases and two deaths. There was also cattle plague amongst cattle in the dairies. Shanghai has its municipal abattoir, but during the year 1907 no animal was rejected on account of tuberculosis, evidence, Dr. Stanley thinks, of the extreme rarity of bovine tuberculosis among the local cattle. Good meat is stamped "Killed in municipal slaughter-house," and no meat is allowed to be sold from any shop or taken into the settlement unless it bears a municipal stamp. Meat inferior in quality but free from disease is passed for sale on stalls only and marked "second quality." Would that English towns would follow this Shanghai example.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN 76 of the largest English towns 8144 births and 4337 deaths were registered during the week ending Sept. 19th. The annual rate of mortality in these towns, which had steadily declined from 15·8 to 14·2 per 1000 in the four preceding weeks, further fell to 13·9 during the week under notice. During the first 12 weeks of the current quarter the annual death-rate in these towns averaged 13·4 per 1000, and in London the mean rate in the same period did not exceed 12·5. The lowest annual death-rates in these 76 towns during the week under notice were 3·7 in Bournemouth, 4·5 in West Bromwich, 6·7 in Hornsey, and 6·9 in East Ham; the rates in the other towns ranged upwards, however, to 19·6 in Grimsby and in Merthyr Tydfil, 20·9 in Wigan, 21·9 in Stockport, and 23·5 in Great Yarmouth. In London the death-rate during the week was 13·9 per 1000. The 4337 deaths from all causes in the 76 towns showed a further decline of 96 from the decreasing numbers in recent weeks, and included 677 which were referred to the principal epidemic diseases, against 1343, 1067, and 840 in the three preceding weeks; of these 677 deaths, 507 resulted from diarrhœa, 43 from diphtheria, 38 from whooping-cough, 36 from measles, 28 from scarlet fever, and 25 from "fever" (principally enteric), but not one from small-pox. The deaths referred to these epidemic diseases during the week were equal to an annual rate of 2·2 per 1000, against 4·3, 3·4, and 2·7 in the three preceding weeks; in London the death-rate from these diseases did not exceed 2·1. No death from any of these epidemic diseases was registered last week in Bournemouth or in Hastings, whereas the annual death-rates therefrom ranged upwards in the other large towns to 5·3 per 1000 in Rochdale, 5·6 in St. Helens, 6·2 in Hull, and 7·6 in Stockport. The deaths attributed to diarrhœa in the 76 towns, which had declined in the four preceding weeks from [illegible] to 668, further fell to 507 in the week under notice. The highest death-rates last week from this cause were 4·8 in Birkenhead, 5·0 in St. Helens, 5·2 in Hull, and 6·6 in Stockport. The 43 deaths referred to diphtheria showed a further increase upon recent weekly numbers, and caused the highest death-rates, 1·2 in Derby and 1·3 in Reading. The 38 fatal cases of whooping-cough showed a marked decline, and were fewer than in any previous week of this year. The 26 deaths from measles somewhat exceeded the low number in the previous week; this disease caused a death-rate last week equal to 1·2 in Rochdale and to 1·5 in Oldham. The 28 fatal cases of scarlet fever included nine in London and its suburban districts, three in Birmingham and King's Norton, eight in Liverpool and Bootle, and three in Manchester and Salford. The 25 deaths referred to "fever" showed a decline of nine from the number in the previous week; the two fatal cases in Wigan were equal to an annual rate of 1·2 per 1000. The number of scarlet fever patients under treatment in the Metropolitan Asylums and the London Fever Hospitals, which had been 2855 and 3005 in the two preceding weeks, had further risen to 3285 on Sept. 19th; the number of new cases of this disease admitted to these hospitals during the week under notice were 625, against 377, 395, and 472 in the three previous weeks. The deaths in London referred to pneumonia and other diseases of the respiratory organs, which had been 102 and 124 in the two preceding weeks, further rose to 137 last week, but were nine below the corrected average number in the corresponding week of the five years 1903–07. The causes of 42, or 1·0 per cent., of the deaths registered in the 76 towns last week were not certified either by a registered medical practitioner or by a coroner. All the causes of death were again duly certified in Manchester, Leeds, Bristol, West Ham, Bradford, Newcastle-on-Tyne, Leicester, and in 47 other smaller towns during the week under notice; eight uncertified causes of death were, however, registered during the week in Birmingham, six in Liverpool, four in Sheffield, three in Preston, and two in South Shields.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in eight of the principal Scotch towns, which had been equal to 15·4, 14·8, and 13·7 per 1000 in the three preceding weeks, rose again to 14·4 in the week ending Sept. 19th. During the first 12 weeks of the current quarter the annual death-rate in these eight towns averaged 13·8 per 1000 and exceeded by 0·4 the mean rate during the same period in the 76 English towns. Among the eight Scotch towns the death-rate during the week under notice ranged from 7·4 and 10·0 in Perth and Aberdeen to 16·1 in Dundee and 16·6 in Glasgow. The 508 deaths in the eight towns showed an increase of 24 upon the low number in the previous week, and included 65 which were referred to the principal epidemic diseases, against numbers declining from 107 to 87 in the four preceding weeks; of these 65 deaths, 35 resulted from diarrhœa, ten from whooping-cough, nine from "fever," seven from diphtheria, and two each from measles and scarlet fever, but not one from small-pox. These 65 deaths were equal to an annual rate of 1·8 per 1000, which was 0·4 below the mean rate from the same diseases in the 76 large English towns. The deaths attributed to diarrhœa in the eight Scotch towns, which had ranged from 63 to 52 in the four preceding we the more recent Tesla current owed their therapeutic power chiefly to suggestion.

Local Tuberculin Reactions.

At the Royal Frederic Hospital Dr. A. Erlandsen has been carrying on an investigation into the diagnostic value of local tuberculin reactions. In the first place he draws attention to the fact that the ordinary method of testing an organism for tuberculosis by repeated injections of increasing quantities of tuberculin is faulty, because the repeated injections tend to bring about a sort of "sensibilisation" of the organism, with the final result that there may occur a reaction subsequently to the last injection, though in reality the organism is free from tuberculosis, at least in any active form. Therefore, the local tuberculin reactions are to be preferred. Their great advantage is that they may be repeated, the cutaneous reaction even any number of times, without bringing about any "sensibilisation" of the organism. The ophthalmic reaction is very trustworthy and occurs in about the same number of patients as the reaction after subcutaneous injections of tuberculin. The cutaneous reaction as introduced by von Pirquet is exceedingly sensitive; in fact, far too sensitive to be employed in adults, nearly all of whom show reaction, as von Pirquet has stated. The reason is probably that all adults carry one or more tuberculous lesions; from which, however, they have recovered, perhaps long ago, while only a restricted number of adults are suffering from active tuberculosis. Dr. Erlandsen has now shown that it is possible to modify von Pirquet's reaction (by weakening its sensitiveness) in such a manner that the reaction takes place in only the same relative number of persons as after the ophthalmic test. Instead of using von Pirquet's solution (25 per cent. Alttuberkulin) he employs a solution of 1 per cent. and covers the scarification with absorbent cotton one minute after the application of the solution, so that the solution cannot become more concentrated by evaporation. The results of this modified cutaneous test coincide pretty well with those of the ophthalmic test. In cases of clinically undoubted tuberculosis in adults there was positive reaction in 100 per cent., while persons in whom tuberculosis could not be clinically demonstrated reacted only in 18 per cent. Dr. Erlandsen's modification of the von Pirquet test must therefore be regarded as an easy and sound method of examining the organism for tuberculosis.

Small-pox.

An epidemic of small-pox has recently occurred in Christiania. It seems to be of a mild character and so far only a few deaths have been recorded. Amongst them is that of a medical man. Upwards of 100 cases are under treatment, and it is now confidently expected that the epidemic has reached its acme.

Sept. 21st.

CANADA.

(FROM OUR OWN CORRESPONDENT.)

Annual Meeting of the American Public Health Association.

THE thirty-sixth annual meeting of the American Public Health Association took place in Winnipeg, Manitoba, Canada, on August 25th, 26th, 27th, and 28th, under the presidency of Dr. Richard H. Lewis, Raleigh, N.C., U.S.A., with Dr. Charles O. Probst, Columbus, Ohio, U.S.A., acting as general secretary. It was one of the best meetings ever held and included a large number of members from Canada, the United States, and Mexico. 73 new members were added to the register. A strong local committee of arrangements had matters in charge and it consisted of medical men from Winnipeg, the provinces of Manitoba, Saskatchewan, and Alberta. Those particularly in charge were Dr. R. M. Simpson, chairman of the Manitoba board of health, Winnipeg; Dr. A. J. Douglas, medical health officer of Winnipeg; and Mr. E. M. Wood, secretary of the Manitoba board of health. Addresses of welcome were delivered by the Premier of Manitoba, the Hon. R. P. Roblin, and by Mayor Ashdown of the city of Winnipeg.

In his presidential address, Dr. Lewis referred to the recent meeting at the White House, Washington, D.C., called by President Roosevelt to consider the vital question of the conservation of the natural resources of the country which were being wasted with such lavish prodigality, stating that he had had the pleasure of attending, on the invitation of the President of the United States, to represent the American Public Health Association. As their organisation had received an invitation to be represented on a permanent committee of that conference he felt it would be wise for them to appoint delegates at the present meeting. Going on to refer to a national bureau of public health for the United States, a project which Canadian physicians were also endeavouring to obtain for Canada, the speaker considered that a national bureau with full powers would eventually weaken the work of the State sanitary authorities and considered that each State, as no doubt he thought each province of Canada, should look after its own health work. In a general way he considered that the kind of bureau required for the United States was one including within its scope and management all the specific health agencies of the Government now in existence, with the addition of others when needed. They would find the chief value in a bureau in its education and information. First, it would educate its own officials and then the health officers of the country; thirdly, the people. He referred to the Bill now pending before the United States Congress which would enlarge the powers and duties of the Public Health and Marine Hospital Service of that country, under which authority will be given for the establishment of a school of hygiene for the training of as many health officers free of charge. He considered that the natural, logical, and efficient teacher of hygiene was the family physician and advocated the education of the people by literature and popular lectures. In his opinion they should definitely and positively endorse the Public Health and Marine Hospital Service, advocating at the same time its further enlargement by the transfer to it of such agencies as *legitimately* come within a bureau. If they refused and made a national bureau with a Cabinet Minister in charge they ran a good chance of getting nothing. He referred to the repeated failures of the great American Medical Association in securing a national bureau with a secretary in the Cabinet, which went to prove that it was futile to try any further. He considered that the period which they were now entering on would be known in the histories of the countries as the period of hygiene.

Two papers contributed by Dr. J. Chico of Mexico City on the subject of Vaccination attracted a great deal of attention and subsequent discussion. Another on the same subject by Dr. Francisco de P. Bernaldez of Mexico, or, more properly, Methods of Practising Vaccination with Human Lymph, also came under this discussion. The latter related his method of performing vaccination as follows. The region in which the vaccine is to be inserted is washed with sterilised water, soap, and a brush, the skin being rubbed until it becomes red, and then dried with sterilised cotton. The lancets are dipped into boiling water or passed through the flame of an alcohol lamp. The pustules are cleansed entirely with sterilised water and cotton; are very superficially scarified and not used if they bleed; a small quantity of lymph is taken up on the lancet and the inoculation is made in the person to be vaccinated by means of small punctures almost adjoining each other and from six to eight in number. The lancet leaves the lymph spread over the place where the punctures have been made. The punctures do not reach below the dermic layer of the skin. The object is to produce pustules in a series, making only one scar, numerous pustules, and painless vaccination. They may be easily examined to find whether they present the characteristics of true vaccination. Any other method leaves the operator in doubt as to whether the individual has obtained immunity or not. Dr. Miguel Merquez of Chihuahua, Mexico, followed, with a paper dealing with the best methods from 20 years' experience. His experience he obtained in over 30,000 vaccinations. He agreed with his colleague from Mexico that puncture was a better method than scraping, and that animal vaccine was safer than human. Although he had been using humanised lymph for many years, he had never noticed cases of syphilis transmitted through vaccination; therefore vaccination from arm to arm might continue in countries where there were no scientifically organised institutes for the culture of animal vaccine. Dr. James Roberts, medical health officer, Hamilton, Canada, then read a paper on the Diagnosis

Correspondence.

"Audi alteram partem."

A FOREIGN BODY IN THE STOMACH FOR SIX MONTHS.

To the Editor of THE LANCET.

SIR,—An infant of eight months old was brought to me this evening with the following story. When eight weeks old the child had swallowed an indiarubber teat; the mother gave her a dose of castor oil and watched the motions to see if the teat would pass through, but found no signs of its doing so. The child has been in good health and has not been seen by a doctor until a fortnight ago, when I saw her for a slight bronchial attack. This morning the child had breakfast of warm milk with a little bread crumbs in it and soon after vomited and in the vomit was the teat inclosed herewith. The child is a healthy-looking, well-nourished baby and seems perfectly well, so if the story is true the presence in the stomach of a large piece of vulcanised rubber has given rise to no symptoms and has not affected the child's growth or strength in any way.

I am, Sir, yours faithfully,

LAUNCELOT ARCHER.

Vincent-square, Westminster, Sept. 18th, 1908.

⁂ We have received the teat which is in two pieces and is stained slightly yellow.—ED. L.

THE MEDICAL DIRECTORY.

To the Editor of THE LANCET.

SIR,—May we ask for the courtesy of your columns to announce our intention of reverting in the 1909 issue to the old plan upon which the "Local List" for London was arranged, namely the division of Inner London into streets in preference to districts. We thank your correspondent "Non Œdipus" and other gentlemen who have written to us for the expression of their views on this subject.

We are, Sir, yours faithfully,

J. & A. CHURCHILL.

Great Marlborough-street, London, W., Sept. 18th, 1908.

THE MEDICAL ASPECT OF GASTRO-ENTEROSTOMY, BASED ON 128 OPERATIONS AT THE MANCHESTER ROYAL INFIRMARY.

To the Editor of THE LANCET.

SIR,—It is difficult to thank Dr. Leech adequately for the temperate and judicial analysis of the cases in which gastro-enterostomy has been performed in the Manchester Royal Infirmary, published in your issue of Sept. 19th. I do not think any surgeon will feel disposed to cavil at the conclusions at which he has arrived, especially that conclusion which has reference to the disastrous consequences of delay. But there is one point telling strongly in favour of early operation which Dr. Leech has not mentioned, and which certainly deserves to be taken into consideration in weighing the merits or the demerits of this operation. There were 46 cases of malignant disease. In one of these the growth was a secondary one; in two others the situation is not mentioned. These may be left upon one side. In 40 out of 43 the growth was at the pylorus—the part of the stomach in which chronic ulcer is most common. In what proportion of these 40 cases did the growth originate at the site of an old ulcer, which had failed to heal under medical treatment and which would at least have had a chance of healing if timely gastro-enterostomy had been done?

It is notorious that in every part of the body, stomach included, carcinoma is especially prone to develop at the site of an old ulcer which is prevented from healing; and the identity of situation in such a large proportion of cases is most significant. It is not the least argument in favour of early gastro-enterostomy that, in addition to the relief it gives, it will, by enabling a chronic ulcer of the stomach to heal more readily, diminish the frequency of gastric carcinoma.

I am, Sir, yours faithfully,

C. MANSELL MOULLIN.

Wimpole-street, W., Sept. 20th, 1908.

THE PREVENTION OF TUBERCULOSIS (IRELAND) BILL.

To the Editor of THE LANCET.

SIR,—In THE LANCET of Sept. 19th, p. 901, Dr. J. C. McWalter, writing in reference to the Prevention of Tuberculosis (Ireland) Bill, says: "Knowing what I do of the Irish people, I believe that the Compulsory Notification Clauses will excite so much suspicion and dread as effectually to undo any good results heretofore obtained from the tuberculosis campaign. People simply will not go to a medical man if they think that by so doing they may be listed as tuberculous."

Now, Sir, while Dr. McWalter gives no evidence of any kind beyond his own individual opinion in support of such a prophetic view he totally ignores the following facts: 1. In places where there is compulsory notification (and here we are dealing with practical experience and not with mere theoretical opinion) no difficulty of this kind has arisen. If practical experience in Sheffield, Edinburgh, Bolton, and New York (where there are so many people from Ireland) has clearly demonstrated that there are no serious objections to compulsory notification, why should there be any in Ireland? 2. At the meetings held in connexion with the Tuberculosis Exhibition all over Ireland resolutions were passed by the people of Ireland calling upon the Government to legislate upon certain points regarded as essential and one of these was the compulsory notification of tuberculosis. Then a deputation of almost everybody who could speak with authority in Ireland on such a question waited on the Lord Lieutenant, the Chief Secretary, and the Vice-Chairman of the Department of Agriculture on Nov. 29th, 1907, asking that special legislation should be introduced without delay with the object of making it compulsory that all cases of pulmonary tuberculosis should be notified; and, finally, on August 27th, 1908, at a large conference of delegates summoned from all parts of Ireland, a resolution was carried with only two dissentients heartily approving of the principles of the Tuberculosis Prevention (Ireland) Bill and earnestly desiring to [illegible] passed into law. Does Dr. McWalter really believe that the people who were at these meetings and on this deputation would have taken such a line of action had they for one moment imagined that the compulsory notification clauses would cause any annoyance, or that the people would object to them, or that they would impale for life persons notified? Ireland enjoys the unenviable notoriety of losing close upon 12,000 of her people every year from tuberculosis—that is, 15 per cent. of all the deaths in Ireland are from tuberculosis. Is this to continue or is she not to be allowed, if her people wish it, to take her position with those in the van in trying to get rid of a largely preventable disease?

Let us discuss this problem in a thoroughly scientific and practical way.

I am, Sir, yours faithfully,

JOHN BYERS.

Belfast, Sept. 21st, 1908.

A QUESTION OF SOBRIETY.

To the Editor of THE LANCET.

SIR,—The regret expressed by "M.D." at finding himself at variance with me seems to me uncalled for, for I cannot find anything in his account of himself or of his cousin that conflicts with the opinions I hold on the nature of drunkenness. Perhaps the account of my address, to which you courteously gave the hospitality of your columns, was so much compressed as to be obscure. A full report will appear in the October number of the *Journal of Mental Science*, and if "M.D." will do me the honour to read it there, or in a copy which I shall be happy to send him on request, I am confident that he will find his criticism unnecessary. Few people have preached, more insistently than I have, the doctrine of the inescapable responsibility of every man for his own acts; and many a trouncing have I had from my colleagues for such preachments. That I should now be accused of supporting the opposite opinion is startling, and impels me to declare that the abstract of my address was military employ are undoubtedly *au fait* with operative surgery, and cantonment general hospitals give them every facility for numerous operations, both major and minor.

A Gloomy Year in the Punjab.

The year 1907 was a very gloomy one in the history of the Punjab; a wet spring, a dry autumn, high prices, and an appalling mortality from plague combined to produce a depression which reacted on the birth-rate. The birth-rate of the year (40·8 per 1000) was badly below the average of the last five years and on this occasion it is clear that the explanation usually offered to account for a decline in the birth-rate—namely, the prevalence of malarial fever in the preceding autumn—is the correct one. The figures quoted in the report indicate at all events that the greatest decline has occurred not in the districts which were most affected by plague but in those where the deaths from malaria were most numerous in 1906. The birth-rate was, as usual, lower in the larger towns than in the rural districts. The comparatively low birth-rate in towns has formed the subject of comment for many years and is, it may be remarked, a feature common to the United Provinces and Bengal as well as to the Punjab. The birth and death registers have been checked in very many cases and there is reason to believe that these statistics are more accurately kept than is usually supposed. Mortality from plague reached the terrible figure of 666,501, and since the inception of the disease in the Punjab 2,021,779 deaths have been registered.

The Pasteur Institute.

An assistant director has been appointed for the Pasteur Institute on the hills and will arrive shortly. The officer selected is Captain A. G. McKendrick, I.M.S., of the Kasauli Institute. During the past seven months 135 patients have been successfully treated at Coonoor and the support obtained by the institution is liberal. The Government of India gave Rs. 3500 and the Madras Government a like sum; Bombay contributed Rs. 1500 and Ceylon and Mysore Rs. 500 each, while Travancore paid Rs. 100.

The Inspection of Factories.

We have heard often of the insufficiency of factory inspection in India, but in the Central Provinces the complaint is coming to be that there is too much of it. For some reason or other it is in Berar that the zeal for inspection rages with particular severity. In this division alone it appears that the establishments exposed to inspection underwent the operation 679 times during the year 1907. Of these 230 were performed by the official inspectors, 181 by magistrates, and 268 by civil surgeons. It is not specified how many factories there are in Berar, but the figures suggest that the managers, who must sigh for the old days of Hyderabad Residency rule, must find their chief occupation in preparing for inspection or carrying out the suggestions of the last visitor, and the Commissioner has been induced to observe that these are not always consistent and that there are too many of them. The Chief Commissioner is of the same way of thinking and promises to deal with the matter as soon as the orders of the Government of India on the Factory Commission report are issued. The point to aim at is evidently to keep the business to the professional inspectors, and to avoid oppressing industry under a multiplicity of miscellaneous inspections by officers who if they take any interest in the subject are liable to be faddists. It is agreeable to know that the result of so much activity has been to bring out the fact that the health of the operatives is everywhere good and that the sanitary conditions, with few exceptions, are satisfactory. The wages of skilled labour, high as they are in the Central Provinces to-day, are reported to be still rising, and yet the difficulty of getting trained hands is a general complaint.

Plague in Bengal.

In the annual report of the Sanitary Commissioner, Bengal, for 1907, some interesting facts are given regarding plague and the measures taken for dealing with it. There was a recrudescence of the disease during the year, the deaths being nearly 84,000, as compared with about 60,000 in 1906. The figures are small compared with those in the United Provinces and the Punjab, but certain districts suffered severely. In Saran some 11,000 persons died in April alone and in Patna district the mortality during that month was 7800. Inoculation is still looked upon with great disfavour, and though the report states that it appears to be gradually gaining in popularity the returns show that only a few thousand people submit themselves yearly to this measure of precaution. Outside Calcutta the inoculations were 2766, of which a considerable number were performed in the Gaya Jail. The adult population still regards inoculation with suspicion, though the more enlightened do not so much object to presenting their children. The measures taken to check an epidemic are such as appeal to the people themselves. *Evacuation* is principally relied upon and in rural areas the villagers readily carry this out. Chemical disinfection has practically been given up; it is resorted to only in special cases, where it is asked for and where it can be properly supervised. An effort is being made to instruct the people regarding preventive measures by the distribution of leaflets in the vernacular. In the board schools of the Saran district the students are taught the first principles of prevention, and their knowledge is tested on the occasion of each inspection. Popular lectures have also been given, but it must take time to break down the ignorance of the mass of the people. The campaign against rats started in 1905 was suspended for three seasons. In the first place it was found to involve great expense; then, although millions of rats were destroyed, the daily returns of numbers killed showed no signs of diminishing; and it was believed that the people would take to this measure without official aid, as they saw that the experiment was a success by causing a decrease in plague. It is not stated whether this anticipation was realised. In Calcutta the number of rats killed was very large, a small reward being given on presentation of batches of tails, but the special health officer doubts whether any permanent impression has been made upon the rat population of the city. Bengal as a whole cannot be said to have been badly afflicted with plague and there is not the need for the special measures which have had to be taken in other provinces. If certain districts in Behar could be purged of the disease the mortality returns would be very low, though we must expect to see some thousands of deaths in Calcutta yearly until the sanitary condition of the native town is improved. When the great scheme for opening out the overcrowded areas is given effect to the worst effects of plague should disappear.

Sanitation of Mussooree.

Sir John Hewitt, Lieutenant-Governor of the United Provinces, has just visited the important hill station of Mussooree which is the summer headquarters of the 7th (Meerut) Division and has given to the municipal authorities a subsidy of Rs.25,000 (£1562) a year for six years towards sanitation and the new piped water installation.

Burial Grounds in Calcutta.

The disposal, by burial or otherwise, of the dead is always a difficult problem and the Calcutta health officer, Dr. T. F. Pearse, has issued a tabulated list of the burial grounds and burning ghats within and without the city that are used for the disposal of the dead bodies of persons belonging to Calcutta. From this list it is ascertained that there are in all over 200 such burial grounds and burning ghats. As regards the latter, there are in all only three burning ghats, comprising the Nimtollah and Kasee Mitter burning ghats in Strand Bank-road and the Shamnagore burning ghat in Tollygunge. These three ghats are under the control of the corporation. Regarding the burial grounds, there are altogether 199 grounds used for the burial of the dead. These are classified under several heads. Six of them are under municipal control. Of other public burial grounds there are 37, five controlled by the Christian burial board, nine by the Mahomedan burial board, while the remaining 23 are Government burial grounds. There are a large number of private family burial grounds, comprising nearly half the entire total. Of the 49 which are registered six are for public use and 43 for family use only. In all 149 burial grounds are contained in the above and these constitute the entire number of grounds in use, the remaining being no longer in use. Of the total number of 199 burial grounds, the Mahomedan community alone have 127 grounds for the disposal of their dead, including both public and private grounds, in and out of use. There are only a few Hindu burial grounds and the remainder consist of burial grounds for all other races and creeds, and include the crematorium which is open to all creeds and castes.

obstinate cases but, although continued over several months, I have never observed any toxic effects.

I am, Sir, yours faithfully,
Mansfield-street, W., Sept. 21st, 1908. H. LYON SMITH.

SPASTIC CONSTIPATION.

To the Editor of THE LANCET.

SIR,—In the annotation on Spastic Constipation, published in your last number, it is stated with truth that the condition has "not received the attention in this country which its frequency warrants." But Dr. Gustav Singer falls into a common error when he ascribes its recognition to Gherchevsky in 1883, as an excellent account of the condition was written half a century earlier by an Englishman. In 1830 John Howship, surgeon to St. George's Infirmary, London, published a small book of "Practical Remarks on the Discrimination and Successful Treatment of Spasmodic Stricture in the Colon, considered as an occasional cause of habitual confinement of the bowels." He describes how in some cases of constipation "the complaint does not so much consist in a defective power of contraction in the whole extent, as in a deficient freedom of relaxation in some one part of the intestinal canal." It should also be remembered that enterospasm, an important article on which was published by Dr. H. P. Hawkins in the *British Medical Journal* in January, 1906, is another name for the same condition, and that many people in England who are unfamiliar with the term "spastic constipation" are well aware of the comparative frequency of "enterospasm."

I am, Sir, yours faithfully,
London, Sept. 23rd, 1908. ARTHUR F. HERTZ.

SOME DISCURSIVE REMARKS ON THE REARING OF CHILDREN IN LONDON.

(BY A SPECIAL CORRESPONDENT.)

I.

THE CARE OF INFANTS IN TOWNS.—CONTINENTAL SCHEMES.—THE CHELSEA KITCHENS.—THE ST. PANCRAS SCHOOL FOR MOTHERS.

THE schemes set on foot by public bodies and by private philanthropic workers to combat the sickness and especially the high rate of mortality which prevail among city-born children are now very numerous. It is much to the credit of the public opinion that it should be so, and it is good to know that all such schemes have had their starting point in the scientific, clinical, and statistical information supplied by medical men. The decreasing birth-rate of this country, coupled with an infantile mortality which, though good compared with that of the United States and many continental States, is still unduly high, has aroused those willing to do something more than to talk about race decadence to make some organised attempts to improve matters. Of all modes to check infant sickness and mortality the improvement of the milk-supply is, of course, the most obvious. Everyone has been able to see that the purer the milk-supply the better in every respect would be the health of mothers and children, whether we are talking of infants who are unfortunately not able to be breast-fed or of babies who have reached the normal age for an independent food-supply. Attention has therefore for a long time, though in no systematic way, been paid to the milk-supply of the young, and this with full knowledge that questions of housing and questions of parental ignorance were at least as important. For a clean milk-supply is a good deal wasted on a parent who does not know what to do with it and has nowhere to keep it. The workers in the cause of infant health have most of them felt that the housing of the poor was the biggest thing of all, but they saw also that if they withheld their efforts until this immense matter was dealt with there would be endless delay. But they saw that they could do much to combat the poverty and ignorance of many mothers of the lower class by systematic instruction in the treatment of their offspring, so as to help them to nourish their infants properly by suckling and to demonstrate to them that breast-feeding is the natural and most healthy manner in which to rear an infant. The object of writing these articles, which I have called "Discursive Remarks"—for they are no more—is to give the results of some personal observations of certain of the plans which have been adopted in London during the past few years to afford the children of the poor a fair opportunity of becoming physically useful citizens.

I will first describe the schemes now in working order in London to promote breast-feeding among poor mothers. The point here is what has been *done*—not what has been *written*. It is of no use at all to write in medical journals, and not much use to write in lay journals, advocating breast-feeding. A certain amount of public attention is aroused and some workers may thus be stimulated to action, but the poor are not themselves directly influenced by anything that is written on the subject. The very poor, speaking generally, do not read at all, or if they do they take no heed to advice on such matters from a printed page. The sole means of reaching their intelligence is to get into personal relations with them, so as to urge them by word of mouth to give their offspring fair play, while assisting them in a material manner to suckle their children and otherwise to bring them up in accordance with the main laws of health. But this is not always easy, as many enthusiastic workers have found. There have been narrow and intolerant persons among the visitors of the poor and to win the confidence of those who have suffered from the Jellybys is by no means an easy task. Moreover, it is natural for self-respecting citizens to be jealous of outside interference with their domestic affairs and to resent the invasion of their homes by strangers, while it must be remembered that all mothers who are injudicious or ignorant are not necessarily wastrels. Negotiations to assist the mothers must be conducted with discretion and tact lest natural susceptibilities should be wounded; and when confidence is gained, as a rule, parents, especially young parents, will listen to, and will follow, advice beneficial to the health of their children and themselves. It is easier perhaps to interest the parent in her own health than in that of the children who seem to her to be thriving at least as well as children in her circles generally do. But pregnant mothers are quick to learn, or are already aware, that if they are not adequately nourished the child will be born in unfavourable circumstances and that they may not be able to supply it with fitting nutriment. The first step in the direction of promoting breast-feeding is to see that the expectant and nursing mothers are themselves well fed, and with this end in view several philanthropic schemes are now running in London with a certain measure of success. The feeding of nursing mothers seems to have been first given a trial in Chelsea among London districts, and this was one of the earliest attempts in Great Britain to deal with the matter, although on the continent for several years there have been organised attempts of the sort. The benevolent institution of "Allaitement Maternel" founded by Madame Bequet de Vienne in 1876 for the care of the enceinte poor developed in 1892 into a home in which such women were fed, clothed, and treated. A little latter Madame Coullet launched in Paris, by means of the association known as "Œuvre du Lait Maternel," a free restaurant for nursing mothers. Both these institutions have been noticed before in the columns of THE LANCET. The latter undertaking was at first conducted on a very modest scale, the original restaurant being established in the abandoned shop of a dealer in cast-off clothes. At the present time the association has five free restaurants situated in the poorest parts of Paris and these supply many thousands of free meals to poor nursing mothers. No questions are asked of the applicants for the meals. They may be married or single, but if they are nursing mothers and hungry they are made welcome. A free restaurant on similar lines was established in Nice in 1905 and the Social Union of Dundee opened the first restaurant for nursing mothers in that city in May, 1906.

Mrs. W. E. Gordon, a lady living in Chelsea, inspired by the success of the work done in aid of nursing mothers by Madame Coullet, determined to pursue a similar course in Chelsea. Notice of the project was sent to the district visitors, the medical men and the clergy of the neighbourhood, and to the sanitary inspectors of the borough, as also to the ladies who visit the maternity cases in charge of the obstetrical department of St. George's Hospital. In January, 1906, a room was hired and opened in Arthur-street, Chelsea, at which good meals could be obtained by nursing mothers on payment of 1*d*. The scheme flourished

the last two or three months in Melbourne. Upwards of 40 cases are known to have occurred. Dr. Douglas Stephens is making a special investigation of the subject and his conclusions will be put before the Medical Congress in October next.

Juvenile Depravity.

A somewhat remarkable case of moral perversion is reported from Tasmania. Two children, aged eight and two and a half years respectively, were sent out in each other's company. The elder boy returned alone and stated that his little brother had been "taken by a hyena into the bush." On being pressed he varied his story by saying that the child had been riding on his back and fell off. Finally, the body of the younger child was found hidden in a hole, with extensive fracture of the skull. The elder boy then confessed that he had got tired of carrying his small brother and had hit him on the head with a log of wood and hidden the body where it was found.

Pure Milk.

A deputation of medical men recently waited on the Premier of Victoria to ask for his support in the formation of an institution for the supply of pure milk to infants. The speakers were Mr. G. A. Syme, Dr. A. Jeffreys Wood, Dr. J. Jamieson, Dr. Barrett, Dr. J. W. Springthorpe, and Dr. T. Cherry. The cost of beginning operations was estimated to be £3000, and the Premier practically undertook to find half that amount while the remainder is to be got by voluntary contributions. A protest has been made by a well-known dairy company who "respectfully urge that if a model dairy farm is to be established it be done by the Government through the Department of Agriculture. It will then be under responsible and expert control, and its use as an object-lesson open to commercial criticism. The present proposal places its management under the control of a body composed of scientific men, who would be responsible to nobody and who could, no doubt, if allowed to spend enough money, produce clean milk suitable for infants; but the question of its actual cost would be lost sight of, and the real value of the object-lesson would be lost. If the trade were then expected to follow in the footsteps laid down for them in this way, the immediate result would be a material increase in the price of milk to the consumer, which would be a doubtful way of assisting the poor mothers of this city. The proposed institute would have more than sufficient scope for its energies and its money if it devoted its attention to the question of supervision and distribution, the establishment of depôts in congested centres, and the education of the mothers as to the value of clean milk in the rearing of children, and the care necessary to preserve it when they get it into their houses."

August 18th.

Obituary.

HAROLD LESLIE BARNARD, M.B., M.S. LOND., F.R.C.S. ENG., L.R.C.P. LOND.,

SURGEON IN CHARGE OF OUT-PATIENTS AT THE LONDON HOSPITAL.

THE late Mr. Harold Leslie Barnard, whose death occurred in his forty-first year on August 13th, was a distinguished son of the London Hospital who had worthily won his place upon its staff. He was born in Highbury in 1868 and was a great-nephew of Michael Faraday. He had not intended originally to follow medicine, for after a year's residence in America he worked in the City for three years, but at the age of 20 entered the London Hospital where he gained the first year scholarship. This success was followed up by a career of continuous distinction. Four years after his entry he qualified M.R.C.S., L.R.C.P., and in 1895, three years later, he graduated in both medicine and surgery at the University of London, his B.S. winning him first-class honours. In the same year he took the Fellowship at the Royal College of Surgeons of England and the next year the M.S. at the University of London. During this period he held in succession all the resident appointments at his hospital, to which he became subsequently surgical registrar, and also demonstrator of physiology, and assistant demonstrator of anatomy in the medical school. His first full staff appointment was that of assistant surgeon to the Metropolitan Hospital, a post which he relinquished in 1900 when he was appointed assistant surgeon and also surgical tutor at the London Hospital. He held this tutorship until 1904, when he took up the post of demonstrator of surgical pathology which he retained until his death. He was elected surgeon to the hospital with charge of out-patients in July, 1907. It can be said unhesitatingly of Mr. Barnard that he was possessed of the real scientific spirit and an endless capacity for work. Both in physiology and in surgery he had made such a mark as leaves little room to doubt that he would have earned a wide reputation if death had spared him to fulfil a life which in far too short a time had achieved so much. The work which he did in conjunction with Dr. Leonard Hill on hæmodynamics resulted in many valuable observations and also in the Hill and Barnard's sphygmomanometer which was invented at a time when the clinical importance of the scientific measurement of blood pressure had not attained the recognition which it now enjoys. His principal surgical work was concerned with the abdomen and upon intestinal obstruction he wrote with an undoubted authority. The article in Allbutt's "System of Medicine" on that subject from his pen is likely to remain as a classic piece of literature, founded as it is upon skilful and painstaking investigation. [illegible] and appendicitis engaged much of his attention and he contributed a paper on the former subject to the Royal Society of Medicine. His important communication upon "The Simulation of Acute Peritonitis by Pleuro-pneumonic Disease" appeared in our columns in 1902. He was an excellent operator as well as an excellent observer. A man so prominently connected with the teaching side of the London Hospital and so popular as was Harold Barnard cannot fail to be sadly missed by his students and colleagues. He entered fully into the life of his medical school, as was evidenced by his presidency of its swimming club and vice-presidency of its football, boxing, fencing, and gymnastic clubs, and also of the Hospital Medical Society. His many activities were carried through in defiance of a poor physique, and it is a general opinion amongst his friends that his whole-hearted devotion to work was at least a factor in his untimely death which followed upon cardiac trouble. His funeral took place in Highgate Old Cemetery on August 17th.

EDWARD PERCY PATON, M.D., M.S.LOND., F.R.C.S.ENG.,

DEAN OF THE WESTMINSTER HOSPITAL MEDICAL SCHOOL.

THE teaching staff of Westminster Hospital, which sustained such a severe loss in the death of Bertram Abrahams earlier in the year, has again to mourn an exceptionally brilliant colleague, the sadness of whose early death was intensified by the long and painful illness which led up to it. Percy Paton was one of those rare men whose academical career has been a triumphant march through the honours lists and who have yet emerged from it with a practical and well-balanced mind on which a deep store of learning has left no reproach of bookishness. He was born 41 years ago in Canonbury and received his medical education at St. Bartholomew's, where he enjoyed a distinguished career as a student and became an assistant demonstrator of anatomy. He qualified under the Colleges in 1889 and in the same year took his degree at the University of London, obtaining the University scholarship and gold medal in obstetric medicine and honours in medicine and forensic medicine. He then became a house surgeon at his hospital and later surgical registrar and anæsthetist at the Hospital for Sick Children, Great Ormond-street. In 1891 he proceeded to the M.D. at the University of London, but, deciding on a surgical career, in the following year he passed the F.R.C.S. examination and also took the London B.S. which gained him the University scholarship and gold medal in surgery, a success which he followed up by obtaining the Mastership in 1894. In 1896 he started his connexion with Westminster Hospital, greatly to the advantage of its school, by obtaining the posts of surgical registrar and senior demonstrator of anatomy. Three years later he became an assistant surgeon and in 1906 surgeon in charge of out-patients, after having been elected Dean of the medical school in 1904. These two posts he held until his death. He was also lecturer in surgical pathology at Westminster Hospital and was an examiner to the Society of Apothecaries, first in anatomy and later in surgery. He gained a wider experience in practical surgery than many men of his seniority by his appointment to a surgeoncy at the Mildmay Mission Hospital, of which his strong religious convictions made him a devoted by for the medical man or the midwife, for baby clothes, and for extra help and feeding during confinement. Passing over 5, home visiting, which will be alluded to in a subsequent article, I come to 6. Perhaps the most novel feature of the St. Pancras school is the fathers' evening conferences. These are held on Tuesday evenings with the object of exciting the interest of the male in his domestic affairs. Several well-known men have addressed these meetings and it is thought that, at any rate to some extent, the purpose of the conferences has been attained. If the British father of the quite low class can be aroused to exhibit an intelligent concern in the welfare and health of his family and home much good will be done.

(To be continued.)

THE SANITARY DEFENCE OF THE HEDJAZ RAILWAY.

(BY THE BRITISH DELEGATE ON THE CONSTANTINOPLE BOARD OF HEALTH.)

(Illustrated with Reproductions of Photographs taken by the Author.)

I.—DAMASCUS TO MA'AN.

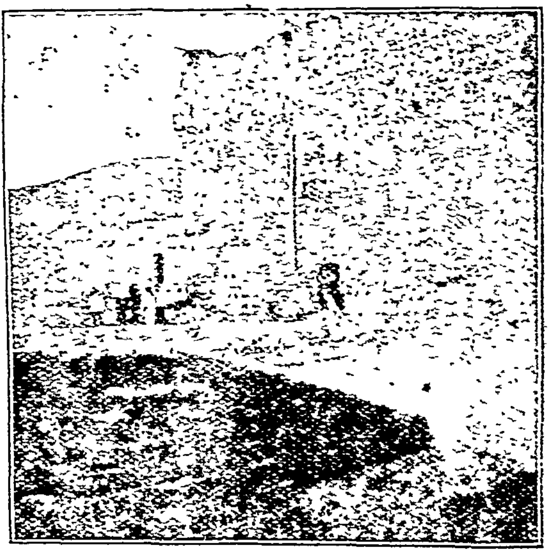
WHEN writing a few months ago the brief article entitled "The Hedjaz Railway and Disease," which appeared in THE LANCET of June 20th (p. 1799), I was quite unaware that very shortly after I should have an opportunity of travelling down the line and visiting most of the places which I had mentioned. This came about in the following manner. On May 19th the Board of Health here decided to send a Special Commission composed of some of its members to the region traversed by the line, with the general object of studying on the spot the question of the sanitary defence of the railway and the special object of selecting the most suitable site for the quarantine station for pilgrims which sooner or later must be brought into being at some point between Damascus and Medina.

The Commission was composed of the Dutch, German, and British delegates on the Board, and a Turkish medical officer in the Sanitary Service, with a second Turkish medical man as "adjoint." The Commission, leaving Constantinople on May 28th, arrived at Beirût on June 1st and at Damascus on June 3rd. In Beirût a sixth member was added to our number in the person of Professor Patch, who holds the chair of chemistry in the American College of Beirût and who accompanied the Commission throughout and undertook the collecting and analysis of specimens of water at the various places visited. In Damascus three more members were added to the mission by the Vali of the Damascus vilayet; these were a major of infantry and a military surgeon, both attached to the administration of the railway, and Dr. Haidar Bey, who, although a medical man, does not practise any longer but follows the business of contractor for public works. He has put up most of the buildings along the railway beyond Dar-ul-Hamra and is now constructing the terminus at Medina. It may be stated in passing that this terminus is being built on an immense scale, the combined length of the platforms running into some kilometres. It should thus be able—as it will almost certainly be called upon—to cope with the arrival or departure of large numbers of pilgrims at a time.

A special train was placed at the disposal of the Commission, consisting of a sleeping-car, an ordinary first-class carriage capable of seating 48 persons, and an empty luggage wagon. In the last the cook and kitchen were installed as well as the provisions for the journey. All stores had to be taken from Damascus, as beyond Ma'an nothing is procurable; the stores for 14 persons (including servants) for an eight days' journey were necessarily of considerable bulk. They included a supply of compressed snow from the Lebanon, which was of great service in the high temperatures met with. The Commission left Damascus on the morning of June 6th and reached Ma'an 25 hours later. Between the two the line traverses the marvellously fertile region of the Hauran and skirts the curious volcanic tract of country known as the Trachonitis. This has been well described as a solidified sea of lava. The black lumps and heaps of volcanic stone which litter the surface of the country offered a striking contrast to the brilliant gold of the standing crops in early June, and no less so did the occasional villages built of this same black-hued stone. Beyond Amman—the Rabboth-Ammon of the Old Testament—the country becomes less and less cultivated, and the true desert gradually begins.

Ma'an is situated in a vast undulating plain of sand and gravel. The station lies at a height of 1074·2 metres above sea level and at a distance of 459 kilometres from Damascus and 943 from Medina. There are two villages, called respectively Ma'an-el-Sham and Ma'an-el-Hedjazié (or Ma'an-el-Misr), both at least one and a half miles from the station and not visible from it. I had occasion to visit them on the return journey on the way to and from Petra. Ma'an-el-Sham is rapidly being abandoned and falling to ruins, while Ma'an-el-Hedjazié is increasing at its expense. Together they contain some four or five thousand inhabitants. Both are typical Arab villages *built of sunburnt mud-bricks.* The latter has plenty of water and is rich with gardens, where figs, vines, palms, and pomegranates grow in abundance, offering a grateful rest to the eye dazzled by the glaring sand all round. There is a *kaimmakam*, or Turkish governor, here; his office is in the old Arab *kala'at*, or fortress, which guards the *burket*, or water-reservoir, as in all the villages along the Pilgrims' Way. Far more often than not, indeed, there is no village at all, and the various places figuring on the map are represented in reality by nothing but the all-precious water reservoir and the high-walled fort to guard it. Between Ma'an and Medaini-Salih, a distance of 496 kilometres, almost the only village worthy the name is that of Tebuk, to be mentioned later.

FIG. 1.



A typical *kala'at* and *burket* (at Akhdar).

The *burkets*, or reservoirs, and *kala'ats*, or fortresses, deserve something more than passing mention. The reservoir has usually solidly built walls and parapets of native masonry; it is square or oblong, with a diameter of some 20 or 30 yards. The depth, from the top of the parapet, may be some 12 or 15 feet; the water is rarely more than from 3 to 5 feet deep. In some the water seems to be constantly renewed from springs and to be fresh and sweet; in others, however, the reverse is the case, and the water is stagnant and covered with an offensive scum. I shall recur to this point when speaking of the water provision for passengers and pilgrims travelling by the line.

The *kala'ats*, or forts, are solid four-square buildings of masonry; they have no outer windows but their walls are pierced by numerous loop-holes for rifle fire. The rooms inside are built round a small courtyard, in which there is usually a well, so that the defenders can withstand a Bedouin attack as long as their provisions last and are in no danger from lack of water. At all the stations along the line,

the last two or three months in Melbourne. Upwards of 40 cases are known to have occurred. Dr. Douglas Stephens is making a special investigation of the subject and his conclusions will be put before the Medical Congress in October next.

Juvenile Depravity.

A somewhat remarkable case of moral perversion is reported from Tasmania. Two children, aged eight and two and a half years respectively, were sent out in each other's company. The elder boy returned alone and stated that his little brother had been "taken by a hyena into the bush." On being pressed he varied his story by saying that the child had been riding on his back and fell off. Finally, the body of the younger child was found hidden in a hole, with extensive fracture of the skull. The elder boy then confessed that he had got tired of carrying his small brother and had hit him on the head with a log of wood and hidden the body where it was found.

Pure Milk.

A deputation of medical men recently waited on the Premier of Victoria to ask for his support in the formation of an institution for the supply of pure milk to infants. The speakers were Mr. G. A. Syme, Dr. A. Jeffreys Wood, Dr. J. Jamieson, Dr. Barrett, Dr. J. W. Springthorpe, and Dr. T. Cherry. The cost of beginning operations was estimated to be £3000, and the Premier practically undertook to find half that amount while the remainder is to be got by voluntary contributions. A protest has been made by a well-known dairy company who "respectfully urge that if a model dairy farm is to be established it be done by the Government through the Department of Agriculture. It will then be under responsible and expert control, and its use as an object-lesson open to commercial criticism. The present proposal places its management under the control of a body composed of scientific men, who would be responsible to nobody and who could, no doubt, if allowed to spend enough money, produce clean milk suitable for infants, but the question of its actual cost would be lost sight of, and the real value of the object-lesson would be lost. If the trade were then expected to follow in the footsteps laid down for them in this way, the immediate result would be a material increase in the price of milk to the consumer, which would be a doubtful way of assisting the poor mothers of this city. The proposed institute would have more than sufficient scope for its energies and its money if it devoted its attention to the question of supervision and distribution, the establishment of depôts in congested centres, and the education of the mothers as to the value of clean milk in the rearing of children, and the care necessary to preserve it when they get it into their houses."

Four years after his entry he qualified M.R.C.S., L.R.C.P., and in 1895, three years later, he graduated in both medicine and surgery at the University of London, his B.S. winning him first-class honours. In the same year he took the Fellowship at the Royal College of Surgeons of England and the next year the M.S. at the University of London. During this period he held in succession all the resident appointments at his hospital, to which he became subsequently surgical registrar, and also demonstrator of physiology, and assistant demonstrator of anatomy in the medical school. His first full staff appointment was that of assistant surgeon to the Metropolitan Hospital, a post which he relinquished in 1900 when he was appointed assistant surgeon and also surgical tutor at the London Hospital. He held this tutorship until 1904, when he took up the post of demonstrator of surgical pathology which he retained until his death. He was elected surgeon to the hospital with charge of out-patients in July, 1907. It can be said unhesitatingly of Mr. Barnard that he was possessed of the real scientific spirit and an endless capacity for work. Both in physiology and in surgery he had made such a mark as leaves little room to doubt that he would have earned a wide reputation if death had spared him to fulfil a life which in far too short a time had achieved so much. The work which he did in conjunction with Dr. Leonard Hill on hæmodynamics resulted in many valuable observations and also in the Hill and Barnard's sphygmomanometer which was invented at a time when the clinical importance of the scientific measurement of blood pressure had not attained the recognition which it now enjoys. His principal surgical [illegible] was concerned with the abdomen and upon intestinal [illegible]struction he wrote with an undoubted authority. The article in Allbutt's "Syst[illegible] subject from h[illegible] of literature, f[illegible] investigation. [illegible] engage[illegible]ch [illegible] paper on the [illegible] subject to the Royal Society of Medicine. His important communication upon "The Simulation of [illegible] Peritonitis by Pleuro-pneumonic Disease" appeared [illegible] columns in 1902. He was an excellent operator as well as an excellent observer. A man so prominently connected with the teaching side of the London Hospital and so popular as was Harold Barnard cannot fail to be sadly missed by his students and colleagues. He entered fully into the life of his medical school, as was evidenced by his presidency of its swimming club and vice-presidency of its football, boxing, fencing, and gymnastic clubs, and also of the Hospital Medical Society. His many activities were carried through in defiance of a poor physique, and it is a general opinion amongst his friends that his whole-hearted devotion to work was at least a factor in his untimely death which followed upon cardiac trouble. His funeral took place in Highgate Old Cemetery on August 17th.

EDWARD PERCY PATON, M.D., M.S. Lond., F.R.C.S. Eng.,

DEAN OF THE WESTMINSTER HOSPITAL MEDICAL SCHOOL.

The teaching staff of Westminster Hospital, which sustained such a severe loss in the death of Bertram Abrahams earlier in the year, has again to mourn an exceptionally brilliant colleague, the sadness of whose early death was intensified by the long and painful illness which led up to it. Percy Paton was one of those rare men whose academical career has been a triumphant march through the honours lists and who have yet emerged from it with a practical and well-balanced mind on which a deep store of learning has left no reproach of bookishness. He was born 41 years ago in Canonbury and received his medical education at St. Bartholomew's, where he enjoyed a distinguished career as a student and became an assistant demonstrator of anatomy. He qualified under the Colleges in 1889 and in the same year took his degree at the University of London, obtaining the University scholarship and gold medal in obstetric medicine and honours in medicine and forensic medicine. He then became a house surgeon at his hospital and later surgical registrar and anæsthetist at the Hospital for Sick Children, Great Ormond-street. In 1891 he proceeded to the M.D. at the University of London, but, deciding on a surgical career, in the following year he passed the F.R C.S. examination and also took the London B.S. which gained him the University scholarship and gold medal in surgery, a success which he followed up by obtaining the Mastership in 1894. In 1896 he started his connexion with Westminster Hospital, greatly to the advantage of its school, by obtaining the posts of surgical registrar and senior demonstrator of anatomy. Three years later he became an assistant surgeon and in 1906 surgeon in charge of out-patients, after having been elected Dean of the medical school in 1904. These two posts he held until his death. He was also lecturer in surgical pathology at Westminster Hospital and was an examiner to the Society of Apothecaries, first in anatomy and later in surgery. He gained a wider experience in practical surgery than many men of his seniority by his appointment to a surgeoncy at the Mildmay Mission Hospital, of which his strong religious convictions made him a devoted here on the return journey and was grateful to find any accommodation.

There is a small garrison at Ma'an, and a considerable number of troops were also camped out in the desert, away to the west of the line; they were said to have come up from Akaba, on their way back from the Yemen. The railway authorities have built a small hospital for their employees close to the station of Ma'an, on the east side of the line. It was built of wood and of far too unsubstantial a nature to withstand the strong winds which so constantly blow here, with the result that the front wall had completely collapsed shortly before our visit here. There is another and more solidly built hospital at Tebuk, further down the line, of which I shall have occasion to speak later.

THE INTERNATIONAL CONGRESS ON TUBERCULOSIS AT WASHINGTON.

(FROM OUR SPECIAL SANITARY COMMISSIONER.)

ON THE ROAD TO WASHINGTON.

New York, Sept. [illegible]5th.

Sanitation at Sea.—Sanitary Laundries for Ships.—The Rival Claims of Passengers and Machinery for Space.—A Modern Solution of the Problem.

To attend the International Congress on Tuberculosis which this year meets at Washington I was about to embark on one of the huge and luxurious floating hotels that cross the Atlantic when it occurred to me that such a journey opened out questions of interest from the public health point of view. There were the ventilation and the drainage of the ships, but there was also the question of general cleanliness. Anyone can see how constantly the decks are scrubbed and the stairs are washed and wiped, and how all is beautifully clean and brightly polished, but what becomes of the soiled linen, of the very towels and cloths with which all this outward cleanliness is maintained? Where do they go and how are they washed? The public does not realise what a huge business this entails. So as not to be dependent on others and also to reduce the expense the great shipping companies should have their own laundry machinery and staff. The placing of the *Lusitania* and *Mauretania* on the line of traffic between Liverpool and New York produced, among many other effects, quite a little revolution in the laundry world. This can easily be understood when it is known that these ships on arriving at Liverpool send ashore all their washing, and this amounts in articles, both large and small, to no less than 65,000 different objects. Such is the extent of what is called the summer wash. But the winter wash is nearly as great because, though there are then not nearly so many passengers, the dirty linen is not landed and washed at New York but brought back to Liverpool, and thus in winter the amount of two voyages is landed and about equals that of one voyage in summer. When all this is washed, ironed, and folded it requires eight large furniture vans packed quite full to carry the linen back to the ship. As there are the other ships besides the two giants mentioned above the Cunard Company had to make provision for washing at their Liverpool works something like 120,000 pieces of linen per week. Considering that any one of these pieces of linen might be the means of conveying infectious disease from one person to another, and as all travellers when once on board have no option but to use the ship's linen, the importance of the laundry question is obvious. So much is this the case that with the advent of the *Lusitania* and the *Mauretania* the laundry at the Cunard works had to be enlarged considerably and reorganised. Consequently, before going on board, I made a point of visiting this new installation.

Of course the first and most difficult problem is that of the steerage passengers, for many of these poor people are far from cleanly in their habits and person. Therefore, without entering the Cunard works at Bootle but from the streets, there is a shoot where specially dirty objects glide down into a basement close to a disinfecting stove. This stove will hold and disinfect by steam under pressure in an hour six horsehair mattresses. It is worth while preserving these and they generally are used by the stewards and the crew. But the steerage beds are of straw and these are simply carted off to the destructor where they are burnt. The stove used is known as Alliot and Paton's steam and vacuum disinfector. When there is any linen known to be infected, such as the linen used in the ship's hospital, this is taken by the port sanitary authorities and disinfected by them; but as an extra precaution it is again disinfected in the company's own stove. Here also is placed all linen containing vermin. When in any cabin or part of a ship vermin are found the linen is placed in a bag to be disinfected as soon as the shore is reached; the cabin itself is rendered airtight and fumigated. Thus all source of nuisance is promptly dealt with and the evil is suppressed.

The chief danger in laundry work rests in the fact that it is not always possible to ascertain when linen is infected. The person who conveys the germs is sometimes not himself aware of his own condition. Consequently it is satisfactory to know that the ordinary normal process of washing is very generally and in itself also a disinfecting process. To my mind, it has always seemed that the chief risk is with the cleanest linen—the towel or the serviette that has only been used once. It is only slightly crumpled, it seems to be quite clean, but it may bear pathogenic germs for all its apparent cleanliness, whereas another towel that is very black and dirty may be quite innocent of any cause of infection. On the other hand, it will require so much washing that even if infected there is every likelihood that the germs will not survive the process of washing. Consequently I was more anxious to watch what was done with the linen that is almost clean. Fortunately, I found that unless linen is boiled the whiteness of its colour cannot be maintained. On the other hand, when linen is very dirty it must not be boiled at first as this would fix the mark of the stains. It has therefore to be soaped and scrubbed and passed through several changes of water before it is placed in boiling water. Ultimately both the dirty and the comparatively clean linen reach the boiling water stage and are thus disinfected by heat during the natural process of washing, not to mention the action of the soap and the passing currents of water. Thus the serviette and the towel may be used in all security.

Of course, the unwashed dirty linen is kept apart and is sorted in heaps corresponding to the methods of treatment to be applied. There are long cylindrical washers, armed inside with wooden knobs that beat the linen and make a lather, which can hold 2000 serviettes. The cylinder revolves and the linen is stirred and shaken as if washed by hand. Then very powerful flushes of water can be discharged in these cylinders, thus replacing a running stream. Indeed, such a lavish use of water is necessary that a new four-inch water main has had to be brought from the street main to the works. To clean the blankets the steam of the engines is used. This soft condensed water is very useful for that purpose. When the linen has been washed or cleaned there are centrifugal hydro extractors capable of 850 revolutions per minute. The cage holding the wet linen is 42 inches wide and when this whirls round at the above rate it soon throws all the water out of the linen. A canvas cover is put over the top to prevent anyone falling in or getting entangled in these powerful machines. On leaving these the linen is ready for ironing. For this purpose a new apparatus has been devised. It is capable of working at 12 different speeds. The heavier and more moist the linen the slower it has to work. This machine consists of two hot revolving cylinders or rollers and the linen is pressed or ironed by passing it between them. This, of course, is an old device, but the machine here used is the latest on the market and the novelty rests in the fact that it is driven by electricity and is 144 inches long, whereas the largest standard size is only 108 inches. This provides about 1100 square feet of ironing surface per minute. There are three such machines working side by side, therefore it is possible to iron 3300 square feet of linen per minute. As it cannot take much less than a minute to iron a serviette by hand it will be seen what an immense saving of human labour has been effected. Furthermore, the action of this machine is so perfect that it is not necessary to starch table-cloths. They get their glossy appearance from the high finish of the machine. Each machine has six feeders who place the linen on the rollers. This work used to be accompanied with some risk as the fingers were sometimes caught and the hand was seriously injured. Now an automatic finger guard has been devised that runs the whole length of the cylinder and if the fingers

the last two or three months in Melbourne. Upwards of 40 cases are known to have occurred. Dr. Douglas Stephens is making a special investigation of the subject and his conclusions will be put before the Medical Congress in October next.

Juvenile Depravity.

A somewhat remarkable case of moral perversion is reported from Tasmania. Two children, aged eight and two and a half years respectively, were sent out in each other's company. The elder boy returned alone and stated that his little brother had been "taken by a hyena into the bush." On being pressed he varied his story by saying that the child had been riding on his back and fell off. Finally, the body of the younger child was found hidden in a hole, with extensive fracture of [illegible] skull. The elder boy then confessed that he had got tired of carrying his small brother and had hit him on [illegible] head with a log of wood and hidden the body where [illegible] found.

Pure Milk.

A deputation of medical men recently wa[illegible] on the Premier of Victoria to ask for his support in the formation of an institution for the supply of pure milk to infants. The speakers were Mr. G. A. Syme, Dr. A. Jeffreys Wood, Dr. J. Jamieson, Dr. Barrett, Dr. J. W. Springthorpe, and Dr. T. Cherry. The cost of beginning operations was estimated to be £3000, and the Premier practically undertook to find half that amount while the remainder is to be got by voluntary contributions. A protest has been made by a well-known dairy company who "respectfully urge that if a model dairy farm is to be established it be done by the Government through the Department of Agriculture. It will then be under responsible and expert control, and its use as an object-lesson open to commercial criticism. The present proposal places its management under the control of a body composed of scientific men, who would be responsible to nobody and who could, no doubt, if allowed to spend enough money, produce clean milk suitable for infants; but the question of its actual cost would be lost sight of, and the real value of the object-lesson would be lost. If the trade were then expected to follow in the footsteps laid down for them in this way, the immediate result would be a material increase in the price of milk to the consumer, which would be a doubtful way of assisting the poor mothers of this city. The proposed institute would have more than sufficient scope for its energies and its money if it devoted its attention to the question of supervision and distribution, the establishment of depôts in congested centres, and the education of the mothers as to the value of clean milk in the rearing of children, and the care necessary to preserve it when they get it into their houses."

August 18th.

Obituary.

HAROLD LESLIE BARNARD, M.B., M.S. LOND., F.R.C.S. ENG., L.R.C.P. LOND.,

SURGEON IN CHARGE OF OUT-PATIENTS AT THE LONDON HOSPITAL.

THE late Mr. Harold Leslie Barnard, whose death occurred in his forty-first year on August 13th, was a distinguished son of the London Hospital who had worthily won his place upon its staff. He was born in Highbury in 1868 and was a great-nephew of Michael Faraday. He had not intended originally to follow medicine, for after a year's residence in America he worked in the City for three years, but at the age of 20 entered the London Hospital where he gained the first year scholarship. This success was followed up by a career of continuous distinction. Four years after his entry he qualified M.R.C.S., L.R.C.P., and in 1895, three years later, he graduated in both medicine and surgery at the University of London, his B.S. winning him first-class honours. In the same year he took the Fellowship at the Royal College of Surgeons of England and the next year the M.S. at the University of London. During this period he held in succession all the resident appointments at his hospital, to which he became subsequently surgical registrar, and also demonstrator of physiology, and assistant demonstrator of anatomy in the medical school. His first full staff appointment was that of assistant surgeon to the Metropolitan Hospital, a post which he relinquished in 1900 when he was appointed assistant surgeon and also surgical tutor at the London Hospital. He held this tutorship until 1904, when he took up the post of demonstrator of surgical pathology which he retained until his death. He was elected surgeon to the hospital with charge of out-patients in July, 1907. It can be said unhesitatingly of Mr. Barnard that he was possessed of the real scientific spirit and an endless capacity for work. Both in physiology and in surgery he had made such a mark as leaves little room to doubt that he would have earned a wide reputation if death had spared him to fulfil a life which in far too short a time had achieved so much. The work which he did in conjunction with Dr. Leonard Hill on hæmodynamics resulted in many valuable observations and also in the Hill and Barnard's sphygmomanometer which was invented at a time when the clinical importance of the scientific measurement of blood pressure had not attained t[illegible] recognition which it now enjoys. His principal surgical [illegible] was concerned with the abdomen and upon intestinal obstruction he wrote with an undoubted authority. The article in Allbutt's "System of Medicine" on that subject from his pen is likely to remain as a classic piece of literature, [illegible] and painstaking investigation. [illegible] and appendicitis engaged much of his attention and he contributed a paper on the [illegible] Society of Medicine. His important [illegible] "The Simulation of [illegible] Peritonitis by Pleuro-pneumonic Disease" appeared in our columns in 1902. He was an excellent operator as well as an excellent observer. A man so prominently connected with the teaching side of the London Hospital and so popular as was Harold Barnard cannot fail to be sadly missed by his students and colleagues. He entered fully into the life of his medical school, as was evidenced by his presidency of its swimming club and vice-presidency of its football, boxing, fencing, and gymnastic clubs, and also of the Hospital Medical Society. His many activities were carried through in defiance of a poor physique, and it is a general opinion amongst his friends that his whole-hearted devotion to work was at least a factor in his untimely death which followed upon cardiac trouble. His funeral took place in Highgate Old Cemetery on August 17th.

EDWARD PERCY PATON, M.D., M.S.LOND., F.R.C.S.ENG.,

DEAN OF THE WESTMINSTER HOSPITAL MEDICAL SCHOOL.

THE teaching staff of Westminster Hospital, which sustained such a severe loss in the death of Bertram Abrahams earlier in the year, has again to mourn an exceptionally brilliant colleague, the sadness of whose early death was intensified by the long and painful illness which led up to it. Percy Paton was one of those rare men whose academical career has been a triumphant march through the honours lists and who have yet emerged from it with a practical and well-balanced mind on which a deep store of learning has left no reproach of bookishness. He was born 41 years ago in Canonbury and received his medical education at St. Bartholomew's, where he enjoyed a distinguished career as a student and became an assistant demonstrator of anatomy. He qualified under the Colleges in 1889 and in the same year took his degree at the University of London, obtaining the University scholarship and gold medal in obstetric medicine and honours in medicine and forensic medicine. He then became a house surgeon at his hospital and later surgical registrar and anæsthetist at the Hospital for Sick Children, Great Ormond-street. In 1891 he proceeded to the M.D. at the University of London, but, deciding on a surgical career, in the following year he passed the F.R.C.S. examination and also took the London B.S. which gained him the University scholarship and gold medal in surgery, a success which he followed up by obtaining the Mastership in 1894. In 1896 he started his connexion with Westminster Hospital, greatly to the advantage of its school, by obtaining the posts of surgical registrar and senior demonstrator of anatomy. Three years later he became an assistant surgeon and in 1906 surgeon in charge of out-patients, after having been elected Dean of the medical school in 1904. These two posts he held until his death. He was also lecturer in surgical pathology at Westminster Hospital and was an examiner to the Society of Apothecaries, first in anatomy and later in surgery. He gained a wider experience in practical surgery than many men of his seniority by his appointment to a surgeoncy at the Mildmay Mission Hospital, of which his strong religious convictions made him a devoted a word concerning the skilful waiting and attendance which so largely help to make such a journey enjoyable. Personally, I am also much indebted to the captain, the purser, and the chief engineer for the time and trouble which they took to facilitate my investigations, and I cannot leave this good ship without expressing my gratitude for their courtesy.

THE SECOND CONGRESS OF THE INTERNATIONAL SOCIETY OF SURGERY.

(FROM A SPECIAL CORRESPONDENT.)

THE International Society of Surgery meets once in three years. The members are elected after nomination by a national committee for each nation and its proceedings are conducted in French, German, or English at the will of the speaker. Every effort is made to limit the membership to surgeons who are in the active practice of their profession, whilst care is taken to select the subjects for discussion sufficiently long beforehand to allow the communications to be in the hands of each member at least a month previous to the meeting. The original paper is written in French, German, or English, but a summary of its contents are issued in all these languages. It is possible, therefore, for each member to follow the train of thought, although he may be ignorant of the language in which it is expressed. The society does excellent work and is highly appreciated by the surgeons of Europe generally, though it appears to have proved little attractive to the surgeons of Great Britain and Ireland.

The second Congress began with a meeting of the members of the International Committee on Sunday, Sept. 20th, when 22 of the 24 members were present, and it was announced that the society numbered upwards of 400 members and that national committees had been formed in Russia, Finland, and Servia. The Congress was opened formally at 9.30 on the morning of Monday, Sept. 21st. Punctually to the time fixed Their Royal Highnesses the Prince and Princess Albert arrived at the Palais Cinquantière, where a magnificent suite of rooms had been placed at the disposal of the Congress by the Belgian Government which had further shown its interest in the objects of the meeting by the grant of a subsidy towards the expense. Their Royal Highnesses were received by M. Davignon, Minister for Foreign Affairs, and by Professor Czerny of Heidelberg, President of the Congress, and every member of the International Committee was presented and received with a few words of welcome each in his own tongue. H.R.H. Prince Albert then entered the large hall, already filled with members, and in a graceful speech declared the Congress open. Dr. Depage, secretary-general, read a list of the members who had died since the meeting in 1905—Mr. Reginald Harrison, Professor von Bergmann, Professor von Esmarch, Dr. Fowler of New York, Professor Terrier of Paris, and Professor Reverdin of Geneva. Their Royal Highnesses then made a minute inspection of the apparatus, maps, and specimens and the real work of the Congress was deferred until the afternoon.

The subjects proposed for discussion were Cancer in all its forms, with especial reference to treatment; Hernia; the Surgery of the Liver; the Surgery of the Spinal Cord; and Anæsthesia, whether Local, Intraspinal, or General. The subject of cancer was illustrated by a magnificent display of specimens which was divided into 14 sections, Germany, England, Austria, Belgium, the United States of America, France, Greece, Hungary, Italy, the Low Countries, Roumania, Russia, Switzerland, and Turkey. The Austrian collection far surpassed the rest, for Professor Wertheim exhibited 250 specimens of cancer of the cervix uteri, whilst Professor Hochenegg, also of Vienna, showed 112 specimens of cancer of the rectum which he had removed by the sacral route. Such a wealth of material enabled the members of the Congress to follow the course of these diseases from the earliest to the latest stages in a manner which would otherwise have been impossible. Professor Wertheim drew attention to the number of specimens in which cancer of the cervix was still in an early stage and attributed it to the instructions constantly impressed upon every Austrian practitioner of medicine to make a digital examination in every case where there were signs of uterine disease. The exhibits of the United Kingdom comprised a specimen of Primary Sarcoma of the Spleen, shown by Mr. D'Arcy Power; a case of Cancer of the Thoracic Duct, shown by Mr. J. Lynn Thomas; some interesting preparations, by Mr. W. Sampson Handley; Drawings of Cancer of the Tongue, by Mr. H. T. Butlin; and a case of Pharmaceutical Products used by Dr. Lovell Drage in the treatment of cases of inoperable carcinoma. In addition to the museum, which was inaugurated by Professor Dollinger of Budapest and carried to a successful issue by the indefatigable energy of Dr. Depage and Dr. L. Meyer, the secretaries of the Congress, there was a good exhibition of instruments and surgical apparatus.

Brussels, Sept. 22nd.

(To be continued.)

BIRMINGHAM.

(FROM OUR OWN CORRESPONDENT.)

The University.

THE return of the number of candidates who have entered for the matriculation examination this year, excluding those who take the examination as a "school-leaving examination," shows an increase of 25 per cent. over the preceding year, the totals being 439, as compared with 355. This definite increase may be taken as an indication that there will be a practically corresponding increase in the number of students in the coming session, in which case the already overburdened accommodation will be still more strained and the longing for the relief which will be given when the physics and chemistry departments can be moved to Bournbrook will be intensified. Fortunately, there is every hope that by next year the relief will be obtained and the more especially cramped departments will be able to expand. The unfortunate death of Professor Churton Collins has removed from the staff of the University a very interesting personality, and it is remarkable that a man who always showed himself so full of life, interest, and hope should have broken down so completely after the strain of the work was over. He will be greatly missed, for he was an excellent lecturer, a most entertaining companion, and he possessed the power of interesting others in his work and ideas.

A Suggested Provident Dispensary.

The medical profession in Birmingham is at present considering a scheme for the establishment of a provident dispensary which has been put forward by a provisional committee, with whom representatives of the council of the Birmingham and District General Medical Practitioners' Union were incorporated. The objects of the scheme are to relieve the ever-increasing pressure on the out-patient departments of the hospitals, to bring about coöperation between several institutions working on somewhat similar lines, to encourage self-help and thrift among the working classes, and to secure to members of the medical profession some slight remuneration for work done. That hospital treatment is sought by cases that can be quite easily and effectively dealt with by the ordinary practitioner is demonstrated by the fact that at the General Hospital the number of out-patients was reduced last year from 65,427 to 62,102 by the simple expedient of referring all trivial surgical cases elsewhere after first-aid had been given and by referring all chronic cases which did not require hospital treatment to general practitioners, clubs, dispensaries, and the Poor-law authorities. Stated broadly, the present suggestion for dealing with patients who have very small means but who are still able to pay something for treatment is that every applicant for admission to membership shall pay 1*s.* as entrance fee and a subscription of 5*d.* a month or 5*s.* a year. The 1*s.* entrance fee will secure the applicant a medical examination and for the subscription he will receive treatment by a medical practitioner, chosen by himself, and medicine from the local branch of the general dispensary. Any registered member of the medical profession who has practised independently in the Birmingham district for 12 months may become a member of the medical staff of the dispensary provided that he does not continue to hold a private medical club. He may decline to accept any individual patient and he will not be required to

The institution is of great value in spreading a knowledge of Western medical science among the Chinese; and in addition to the employment of certain of the licentiates in the public service and in the Chinese dispensaries the senior students have frequently been made use of for various purposes during epidemics. A Government grant-in-aid of $2500 is made to the College to be used as honorariums to the lecturers, who are either Government officials or medical practitioners in local practice. Steps are at present being taken for the provision of adequate buildings for the purposes of the College which has hitherto carried on its work in various lecture rooms and laboratories placed at its disposal by hospitals and other institutions in different parts of the city.

THE HEALTH OF NORTH DEVON IN 1907.—Dr. E. J. Slade-King in his summary of the reports of the medical officers of health of North Devon for 1907, which he has just presented to the Devon county council, states that of an estimated population of 146,775 the death-rate was 14·3, compared with 13·7 in 1906. The annual death-rate per 1000 births under one year of age was 104; in 1906 it was 98·7. 96 deaths occurred from zymotic diseases, giving a death-rate of 0·7 per 1000. Six deaths were due to enteric fever. 467 cases of infectious disease were notified, against 430 in 1906. 101 deaths were due to pulmonary tuberculosis, equal to a death-rate of 0·6 per 1000; in 1901 there were deaths from this disease and in 1906 the number was 1 121 deaths were caused by cancer, compared with 123 1906. The birth-rate was 19·7 per 1000, as against 21 1000 in 1906.

THE EDUCATION ACT IN GLAMORGAN.—Th report of the county medical officer of Glamorgan on t medical inspection of children in public elementary schools has recently been issued. After detailing Section 13 of the Education (Administrative Provisions) Act, 1907, and the steps taken by the local education committee to put that section into operation, a copy of a circular letter is printed which has been addressed to the head teachers of each department of all the schools under the jurisdiction of the education committee advising them as to the procedure to be followed. The work of inspection was commenced on April 27th last and was continued regularly up to the end of July. During the 12 weeks 117 schools were visited and 4021 children were medically examined. Of these, 1979 were boys and 2042 were girls and the results are tabulated in six tables accompanying the report. No fewer than 1360, or 33·8 per cent., of the 4021 children examined in the 117 schools were found with defects capable of interfering to a marked degree with educational progress and this must be regarded as a serious pronouncement. The medical officer thinks that with regard to the proper treatment of defects of vision, defects of teeth, advanced ringworm, adenoids, and enlarged tonsils, there will be considerable difficulty in securing adequate treatment, for, as he adds, "such work is tedious and exacting and consequently the fee it demands is heavy to a large proportion of the working-class people." The medical officer also acknowledges the valuable cooperation in the work of the teachers.

THE WHITE CROSS OF ST. JOHN.—In connexion with the formation of the Devonport Centre of the St. John Ambulance Association Major Robert J. Blackham, R.A.M.C., delivered an inspiring lecture on the White Cross of St. John and its association with the ambulance movement. With the object of reaching a large and influential section of the community who did not hear the lecture it has now been published in pamphlet form with a preface written by the mayor of Devonport. The Red Cross movement of the "sixties," as everyone knows, gave the opportunity to the Order of St. John of Jerusalem to re-establish and to continue the medical and charitable work which had always been a feature of the Order, though it was not till 1877 that the St. John Ambulance Association came into existence as a department of the Order of St. John. In 1888 the Association received its charter from her late Majesty Queen Victoria and the members of the Royal family have ever since taken the keenest interest in its work. In tracing the connexion between the ambulance movement and the Christian hospital founded in 1056 at Jerusalem for the relief of poor pilgrims of all nations who visited the Holy City, Major Blackham has performed a task for which all who read his lecture will be grateful. As he points out, members of the Royal Army Medical Corps must have a very kindly feeling for the Order of St. John, "as these gallant soldier-priests were the first to see that the healing of a man's wounds was a knightly service, and that it was just as much a soldier's work to heal a sick man in a hospital as to kill a healthy one in the field." Major Blackham concludes his lecture with the words: "Thrones and empires, sceptres and States may rise and fall, but the White Cross of St. John, the guerdon of the injured, will never pass away while Christian charity remains to us, or sympathy with human suffering endures."

ANKYLOSTOMIASIS IN COSTA RICA.—Mr. F. N. Cox, H.M. Consul, reports that in the country districts of the interior it has been found that ankylostomiasis, or hookworm disease, has become a widespread malady. A commission of medical men has made a tour in the affected districts and some 3700 patients have been treated with very good effects. Similar tours are to be made annually with a view, in addition to treating any patients that there may be, of teaching the country people to take preventive measures against this disease.

anyone that medical treatment was the treatment which ought to be applied for the elimination of cancer! Many of the cases of cancer in women's breasts were, he said, attributed by them to blows, and from these and the case of *the fireman above quoted* it seemed to him evident that cancer was due to injury. In conclusion, the chairman said it was a remarkable thing that surgeons should continue to use the knife in such cases! It is quite refreshing to find someone who, without any special training presumably, has managed to solve a problem at which for years so many able scientific men have laboured. From the statement it is apparent that not only has the question of treatment been satisfactorily settled but the members of the institution have also apparently strong views on the causation of the disease. It is to be regretted that the methods by which this cure is attained are not more widely known. As is usually the case when such claims are put forward for the cure of such a disease, patients are not lacking and money flows in from public subscriptions to the institution to the tune of £800 per annum.

Dundee Royal Infirmary.

At the last meeting of the governors of this infirmary the announcement was made of the gift by Mr. Robert Sime, Mundamalla, Newtyle, of 1000 guineas to endow a cot in the children's ward to be called the "Mrs. Marjory Sime Cot," in memory of his late wife; also of the generosity of an anonymous donor in providing for the appointment of a lady visitor to read and to speak to such patients as should desire it. Mr. William Rettie, chairman of the directors, presided, and in moving the adoption of the report, commented on the work of the infirmary during the last three months. The number of patients treated, notwithstanding the fine weather, had shown an increase on the corresponding quarter last year, as also did the numbers treated in connexion with the Maternity Hospital. It had to be acknowledged that the finances were in rather a poor way. They had had to take £9000 from the reserve to meet the current account last year, and they had an extra expenditure of something like £3200 on buildings for the present year. In those circumstances the directors made renewed appeal to the community for their generous support.

Sept. 22nd.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

The Difficulty of Pauper Lunatics.

THE monthly meeting of the joint committee of the Richmond District Lunatic Asylum was held on Sept. 17th. The report of Mr. J. O'Conor Donelan, the resident medical superintendent, showed that there are at present in the Richmond and Portrane asylums 1560 male and 1507 female inmates. Since the last meeting of the committee 18 males and 25 females had been admitted. The report went on to point out that a large proportion of the persons who had latterly been admitted were in a very feeble state of general bodily health, many being cases of senile, mental, and bodily decay, who up to recent times were scarcely regarded as eligible for admission to asylums. The growing tendency, on the part of union officials particularly, and indeed of the general public as well, to send all individuals who were suffering from bodily enfeeblement to an asylum was an important factor which tended to give people an exaggerated impression of the number of the insane. In fact, these institutions seem to have come now to be regarded as district infirmaries as well as district asylums. The chairman (Mr. Richard Jones, J.P.) said that he had been constantly endeavouring to stop the immigration into the asylum from the union workhouses of all people who were not proper subjects for care in a lunatic asylum at all and whose faculties had merely declined through old age. They had succeeded to a large extent in excluding these people, but not altogether. He had over and over again enjoined the medical superintendent to refuse to admit these people. A great number of them had been sent to Portrane from the North Union Workhouse. Mr. Donelan said that there was no proper provision in the North Union Workhouse for the care of the insane, and the guardians were at their wits' end to know what to do with their insane charges. One of the members suggested an amalgamation of the unions as a means of relieving the situation to some extent. The discussion is likely to have good effect on the internal economy of both asylum and workhouse in the near future.

Royal Hospital for Incurables, Dublin.

At the monthly meeting of the committee of management of this hospital, which was held on Sept. 10th, it was resolved that—

> We, the managing committee of the Royal Hospital for Incurables, Dublin, unanimously express our strong conviction that the exclusion of Ireland from the operation of the Bill for State Examination and Registration of Nurses would be detrimental to the interests of the nursing profession, and we trust that a clause will be inserted in the Bill now before Parliament placing Irish nurses on the same footing as English and Scotch nurses.

At a meeting of the board of governors of the National Maternity Hospital, Holles-street, a similar motion was carried, the meeting pledging themselves to resist the exclusion of Ireland from the working of the Bill as "grossly unfair to Irish trained nurses seeking employment in England."

Cork-street Fever Hospital and House of Recovery, Dublin.

The managing committee held its usual meeting in the board-room of the institution on Sept. 10th. The medical superintendent's report showed a large increase in the number admitted, which was probably owing to the prevalence of measles and to a large increase in the number of cases of enteric fever. Scarlet fever cases were below the normal in number but of a more severe type. Diphtheria and pneumonia contributed their usual quota. Erysipelas was not prevalent during the month. A large number of subscriptions and donations was thankfully acknowledged.

A Case of Milk Prosecution.

A case which came before the Southern Metropolitan police court on Sept. 18th resulted in a judgment of unusual decisiveness. Mary A. Fagan, of 80, Clanbrassil-street, was summoned by Inspector Nolan, of the public health department of the corporation, for selling to him a pennyworth of new milk which had been adulterated with 13 per cent. of added water. It was stated that the defendant had been fined £10 on May 20th last for a similar offence, and the magistrate (Mr. Drury) adjourned the case until the first Tuesday in October in order to enable the defendant to sell her cows and to give up the business in the meantime. If this were not done he announced that he would impose a sentence of two months' imprisonment. If all such milk-dealers were treated on corresponding lines, what an inestimable boon it would be to the citizens of Dublin.

A Medical Man's Pension.

The Local Government Board of Ireland has overruled the decision of the Castlerea board of guardians refusing a superannuation allowance to Mr. S. McDermott of Ballaghaderin. He has satisfied it that he was over 60 years of age when the Local Government Act came into force, and this makes his pension compulsory. The Local Government Board of Ireland, that much-abused body, has in this instance been more generous to a medical officer who has grown grey in the honourable and efficient discharge of his poorly requited duties to the helpless substratum of the population than his employers of the board of guardians.

The Samaritan Hospital, Belfast.

As a result of the recent fête the sum of £502 has been handed over to the funds of this hospital.

Severe Weather in the North of Ireland.

There has been scarcely a day during the past fortnight without a heavy downpour of rain accompanied with high wind, with a result that all over Ulster the harvest is in a deplorable condition. Hundreds of acres of corn are uncut, and what has been reaped is lying saturated in stooks in the fields. Flooding has taken place in many of the districts in the North of Ireland.

Down District Asylum.

The report for the year 1907, just issued, shows that at the end of 1906 there were in the asylum 721 inmates, while 158 were admitted during the year 1907, that is, 24 in excess of those of the preceding year. 60 were discharged and there was a recovery rate of 45 per cent. on the admissions. It is very interesting to find that dysentery, the scourge of former years, has almost disappeared from the asylum, there having

Notes, Short Comments, and Answers to Correspondents.

A POINT IN MEDICAL ETHICS.

"M.R.C.S., L.R.C.P." writes: "I shall be glad of your opinion in the following matter. I had been looking for a practice for some months at some seaside town, and I had inspected a number of practices in different parts of the country, but I could find none to suit me. I was given by an agent the name of a practice which was for sale at a seaside town which I will call X. The agent offered an interview with Dr. K., the vendor, who was away *ill*, but I refused this, saying that I could not contemplate buying the practice unless the house suited me. I then looked over the house, but as the house was quite unsuitable for my purpose I did not inspect the books or inquire into the details of the practice, but I wrote immediately to the agent to say that I had decided not to buy. After this I inspected practices in other towns, but I was unable to find any which I con[illegible] suitable. Ultimately I determined to start a practice for myself and I took a house in the seaside town X referred to above. In due course I called on all the medical men of the town, but [illegible] I was expecting their return calls I received a 'round robin' signed by five of the medical men saying, 'We, the undersigned, have decided that we cannot return your call. The reason for which you will readily understand.' Apparently the signatories consider that my visit to the house of Dr. K. should have precluded any attempt to settle in the town, although I have informed them that I did not examine any of the books of the practice and did not see the vendor, and I was even particularly careful not to make any inquiries in the town about the practice. I shall be glad to know your opinion of the matter and to have your advice as to the course I should pursue, especially as I find that the statement is now being spread that I carried every possible investigation into the practice, both with the vendor and in the town. Can it be accepted that to view a medical man's house should prevent a medical man practising in the same town?"

*** The above statement seems to us to be a frank explanation of circumstances which ought to have prevented anything whatever in the nature of a combination against the medica[illegible] question by his brother practitioners. If "M.R.C.S., L.R.C.P." had inquired into the details of the practice, or had attempted to obtain any information whatever which he *could afterwards* use to secure gratuitously a practice which he desired, of course the "round robin" would have been justified; but as inquiry would have shown that no inspection of the books had taken place we think that the document was an unfortunate one. In answer to the two questions put to us by "M.R.C.S., L.R.C.P." (1) We advise that the clear statement made to us as to the circumstances of the case should be sent not only to the five signatories to the "round robin" but to all the practitioners in the town and to the secretary of any local medical society or branch of the British Medical Association which may have its centre in the town. (2) It is obvious that to inspect a medical man's house cannot preclude him who makes the inspection from practising in the town if only because there might be two practices vacant simultaneously.—ED. L.

EARLY ENGLISH MEDICAL BOOKS.

To the Editor of THE LANCET.

SIR,—In reference to the correspondence which is appearing in your columns about early English medical books I should say that your correspondent, Dr. Oscar Jennings, is correct in his assumption that the "Governal of Health" is the earliest *printed* medical work in English. It was printed about 1489. The book was written by John of Burgundy, about whom very little is known for certain. So far as I know the earliest medical works in English are some fourteenth and fifteenth century manuscript translations of portions of Hippocrates and some translations into English of John of Burgundy's treatise "De Pestilentia." One of these dates from the fourteenth century and there are many others of the fifteenth century in the Sloane collection in the British Museum.

I am, Sir, yours faithfully,

Sept. 22nd, 1908. M.D.

COEXISTENCE OF TESTES AND UTERUS.

M. Cornil and M. Bossard have presented to the Paris Anatomical Society the contents of the scrotum of a young Greek who was operated on for a tumour. The testicles contained spermatozoa and between them was situated a uterus 10 centimetres in length.

GARBAGE MONGERS.

A PARTICULARLY flagrant case in which an unscrupulous dealer attempted to sell organic poison to the public came before the magistrates at Newry petty sessions on Sept. 16th. A woman of Carrowmanden was summoned by the Newry urban council for having exposed for sale the carcass of a pig unfit for human food. A veterinary surgeon stated that the carcass was partly undergoing decomposition. The bench fined the defendant 6*d*. and £3 7*s*. costs, with the alternative of one month's imprisonment. It is hard to understand why a nominal fine was inflicted. If the alternative sentence were only carried out in a few of these outrageous cases we should not so often have occasion to record them.

MEDICAL DEFENCE UNIONS.

To the Editor of THE LANCET.

SIR,—Can any of my brother practitioners inform me how many unions are there in England which a medical man may join by payment of annual subscription? It is needful in these days for every medical man to join such a union for protection.

Some time ago I found addressed to me an advertisement in which an insurance company was issuing a prospectus to insure medical men against any charge of unskilfulness which a patient may bring. Are there such insurance offices? Thanking you,

I am, Sir, yours faithfully,

Sept. 21st, 1908. PRACTITIONER.

ROGUERY AND CREDULITY.

A CASE which was heard before Judge Lumley Smith on Sept. 15th illustrates well the cynical remark of "the Claimant" about money [illegible]. The plaintiff was a maidservant named Ling, and the [illegible]lant a man named Tom Wallis Rogers who posed as a [illegible]etic healer. Some nine years ago Miss Ling had one of her [illegible] removed and wore a glass eye in the socket. She heard of [illegible]gers and went to see him when he told her that he could cause [illegible] new eye to grow. At first she did not believe him [illegible] walked her over [illegible] her face d[illegible] thumping her back. [illegible] to [illegible]th and paid in all [illegible] 16th [illegible] treat[illegible] that everything was going on [illegible] and that if she di[illegible] treatment she would lose the sight of the other eye. [illegible] APPLETON AND Co[illegible] to the Middlesex Hospital and in consequence of [illegible] General Surg[illegible] there the prisoner was arrested by the police. The [illegible] in giving evidence said that he had 3500 clients. The jury found him guilty and he was sentenced to nine months' imprisonment in the second division. As, however, Dr. W. N. East, the assistant medical officer at Brixton prison, said that he considered the prisoner was of unsound mind, Rogers is to be kept under observation. Rogers's conduct is no worse than that of hundreds of other rogues whose advertisements appear in the columns of apparently respectable magazines and newspapers, and if he is mad there was a great deal of method in his madness. But so long as there exist such credulous persons as Ling for so long will there be rogues to prey on them.

AN ANCIENT PICTURE.

To the Editor of THE LANCET.

SIR,—I am much obliged to Mr. W. Fleming for his information respecting Hannah's picture. What I would like to know are the names of the two courtiers and two physicians who are in the picture besides Harvey, the King, and the Prince of Wales.

I am, Sir, yours faithfully,

Plymouth, Sept. 19th, 1908. M. D. KEILY.

MOTORS AND MEDICINE.

A MEDICAL correspondent sends us the following anecdote. We note that in the recent circular from the Local Government Board concerning motor-cars "excessive use of the horn" is placed among the marks of the inconsiderate driver, but the use on the present occasion of "the hooter" seems to have been fully justified.

"My little boy, aged six, who is much interested in motor-cars, was prescribed an enema by a medical friend. This was administered by his mother by means of a bottle syringe. Next day the doctor asked the small boy how he felt. 'Oh! much better, thank you, since mummy gave me the hooter.'"

PUBLIC HEALTH AS AN OPTIONAL SUBJECT FOR THE DIPLOMA OF F.R.C.S. EDIN.

To the Editor of THE LANCET.

SIR,—Will any of your readers with personal experience of examination in public health as an *optional* subject for the diploma of F.R.C.S. Edin. kindly give me some idea of the scope of the examination and the names of any books which they found useful? The information which you kindly gave me last week is not exactly what I require.

I am, Sir, yours faithfully,

Sept. 19th, 1908. DIPLOMA.

◆

Enquirer.—With regard to the legal points involved our correspondent's best course is to consult a solicitor. Cases of this nature, however, are usually made a matter of compromise and perhaps the fairest arrangement would be that the nurse should be paid half her fee, for it is quite possible that owing to her engagement for the case in question she has lost the opportunity of giving her services to some other case.

ERRATUM.—In a review of Vol. I. of "Archives of the Pathological Institute of the London Hospital," which appeared on p. 878 of THE LANCET of Sept. 19th, the date of publication was given erroneously as "1903." It should have been 1906.

COMMUNICATIONS not noticed in our present issue will receive attention in our next.

During the week marked copies of the following newspapers have been received:—*Birmingham Daily Post, South Wales Daily News, Western Mail, Edinburgh Evening Dispatch, Liverpool Post and Mercury, Manchester Evening News, Birmingham Evening Dispatch, Daily Mail, Daily Chronicle, Wigan Observer, Eastern Morning News, Norfolk Weekly Standard, Chelsea Mail, Grimsby Telegraph, Nature, Pall Mall Gazette, Huddersfield Examiner, Nottingham Evening Post, Blackpool Gazette, &c.*

An original and novel feature of "THE LANCET General Advertiser," is a Special Index to Advertisements on pages 2 and 4, which not only affords a ready means of finding any notice but is in itself an *additional* advertisement.

Advertisements (to insure insertion the same week) should be delivered at the Office not later than Wednesday, accompanied by a remittance.

Answers are now received at this Office, by special arrangement, to advertisements appearing in THE LANCET.

The Manager cannot hold himself responsible for the return of testimonials, &c., sent to the Office in reply to advertisements; copies only should be forwarded

Cheques and Post Office Orders (crossed "London and Westminster Bank, Westminster Branch") should be made payable to the Manager, Mr. CHARLES GOOD, THE LANCET Office, 423, Strand, London, to whom all letters relating to Advertisements or Subscriptions should be addressed.

THE LANCET can be obtained at all Messrs. W. H. Smith and Son's and other Railway Bookstalls throughout the United Kingdom. Advertisements are also received by them and all other Advertising Agents.

Agent for the Advertisement Department in France—J. ASTIER, 31, Rue Bapst, Asnieres, Paris.

man who shall attend a suspicious case is bound to make a similar declaration *to the same authorities* within 24 hours, or, in default of the medical man it must be made by the head of the family with which the patient is dwelling. The penalty for infringing this decree will be imprisonment of from a fortnight to three months. and a fine of from 50 to 500 francs if the offence arises from wilful or negligent disobedience of the special decree, *or* imprisonment of from *three days* to a *fortnight with a fine of from 5 to 50 francs* if there is an infringement of the usual sanitary regulations. The decree further forbids the entry into any land frontier of France of soiled linen, clothing or bedding, rags, and fruits or vegetables which grow on or near the ground. All carriages which have been occupied by a patient suffering from cholera or considered a suspicious case by the sanitary officer are to be disinfected with the least possible delay.

(FROM OUR OWN CORRESPONDENT.)

The Karell Treatment.

ABOUT 40 years ago a Russian physician, Dr. Karell, devised an efficacious method of treating obesity and troubles of the circulation. According to the *Correspondenzblatt für Schweizer Aerzte*, quoted in the *Munchener Medicinische Wochenschrift*, Dr. Lenhartz, chief physician to the Eppendorf Hospital at Hamburg, has recently made an extensive trial of this method, which has hitherto been little employed in Germany. The treatment is indicated especially in chronic bronchitis and emphysema, in certain cardiac disorders, and in cardiac failure following general obesity. The "cure" consists in the administration of 200 cubic centimetres of milk four times a day during five to seven days without any other fluid or solid food. On the following two to six days some other food is allowed together with the milk. First one egg and some biscuits are allowed, then two eggs and some bread, then some meat, vegetables, and milky rice pudding, so that after about a fortnight's treatment a mixed diet is being taken, whilst the quantity of 800 cubic centimetres of milk or tea is the maximum amount of fluid allowed during the next four weeks. The bowels must be looked after during the "cure" and purgatives are required subsequently. The patients, as a rule, tolerate the treatment very well and become accustomed to the reduction of fluid after the first few days. Patients suffering from cardiac weakness and troubles of the circulation are often affected with gastro-intestinal catarrh and consequently have but a poor appetite. The treatment was specially efficacious in arterio-sclerotic myocarditis, whilst in valvular diseases the success was less obvious and in degeneration of the myocardium it failed. The patients must be kept in bed during the "cure." On the third day the dyspnœa and oppression disappear, so that patients who for weeks have often passed the night sitting in a chair can take a good night's rest asleep in bed. Diuresis is also increased and drugs such as digitalis are rendered superfluous.

The Title of "Specialist."

The increasing number of self-styled "specialists" who assume this title without the warranty of real expert knowledge and training has been for long a cause of grievance for medical practitioners; this is very natural, seeing that the general public, especially in the larger towns, has become accustomed to regard the general practitioner as an inferior being and in every case of serious disease to seek the advice of a "specialist." The "medical chambers" and other representative bodies have on several occasions discussed this question and have drawn the attention of the Government to it in the hope of obtaining legislative restrictions. The Prussian Minister of Public Instruction accordingly has recently asked the opinion of the Consultative Medical Board which is attached to the ministry, (the so-called "Wissenschaftliche Deputation"). This body, consisting especially of members of the Berlin Medical Faculty and of medical officers of the higher ranks, has made the following proposals. Medical men desiring to take the title of "specialist" should have to comply with certain conditions. The title of "specialist" should be granted only to medical men who after having qualified have undergone a special training for about three years. This special training must be performed either as an assistant at a university clinic or at an academy of medicine, or in a special department of a general hospital, or to a recognised specialist. A list of the recognised hospitals, clinics, and specialists allowed to train intending specialists should be published every year by the competent authority. The candidate must show certificates of his training. The title of specialist shall be granted for one of the following branches of medicine only: clinical medicine, surgery, diseases of the eyes, diseases of the larynx, the nose, and the ear, obstetrics and women's diseases, diseases of the skin and the urogenital organs, nervous and cerebral diseases, and diseases of children. The Minister of Public Instruction has informed the provincial medical chambers of the proposals of the Medical Board, adding that the Government will abstain from bringing the matter into Parliament for legislation but that it will be the duty of the courts of honour to induce the medical men under their jurisdiction to comply with the above rule when desiring to become specialists. According to the opinion of a great many medical men the course adopted by the Government to leave the matter to the arbitration of the courts of honour is, indeed, much preferable to legislation. It would be extremely difficult to differentiate by law between men rightly entitled and men not entitled to call themselves specialists. This must always be a matter of special inquiry in each individual case, and is therefore better left to the bodies whose duty it is to control the ethical behaviour of the medical profession. The difficulty of legislation is apparent in the very proposals of the Consultative Board which only recognises eight special branches of medicine, leaving apart new methods of therapy which have recently developed, such as radiography, hydrotherapy, &c. Medical men engaged in these methods would therefore be disqualified from attaining the rank of "specialist" if such proposals were to become law. The question will undoubtedly arouse animated discussion during the forthcoming winter season.

Lipomatosis as a Sequel of Castration.

Before the Berlin Society for Psychiatry and Nervous Diseases Dr. Schuster showed the case of a man 47 years of age who had undergone castration for tuberculosis of the testicles. After the operation an enormous development of the fatty tissue took place, so that the chest, the back, the lumbar region, and the shoulders were covered by layers of fat, some regions—e.g., the forearms and the legs—escaping comparatively. The lipomatosis was, on the whole, symmetrical.

(FROM OUR OWN CORRESPONDENT.)

High-Frequency and High-Tension Currents in Neurology.

AT a recent meeting of the Medical Society of Copenhagen Dr. Viggo Christiansen read a paper on the use of high-frequency and high-tension currents in neurology. He said that he had tried the treatment in 121 patients, of which number 56 were suffering from functional nervous diseases, the nervous disorders in the remaining 65 being of an organic nature. He stated as his opinion that the high-frequency current represents a useful augmentation of the suggestive therapeutic means of the neurologist. It may be employed successfully in certain forms of insomnia and is of value in combating hypnotic drug habits. Dr. Fischer had observed very considerable improvement in cases of mental depression with insomnia and urged a trial of the method in all institutions where an x ray apparatus was available. Professor Friedenreich expressed his satisfaction at the sound scepticism of the two preceding speakers with regard to the marvellous effect of the high-frequency current. In his opinion this current proved efficacious in exactly the same cases in which in former days other forms of electricity were considered valuable. For instance, both the faradic and the galvanic current had also been praised as a powerful remedy against insomnia and certain painful affections. But he felt rather convinced that these old-established forms as well as library. Such machinery I regard as essential for the efficient teaching of tropical medicine. It is towards this position of theoretically indicated efficiency that those of us who have been working for the London School of Tropical Medicine for the last ten years have been struggling, and to which, I am glad to be able to say, we have at last attained.

I have prepared a list of the principal tropical diseases with, so far as we know them, their germ causes and intermediaries. These tables (Tables I., II., and III.) indicate in synoptical fashion the leading facts in our present knowledge of the subject, and the many gaps that remain to be filled in. You can see from them how completely the principle I have enunciated as regulating in the main the distribution of tropical disease is substantiated. The tables also show well how much has been accomplished in recent years. If we regard, as I think we may, this recent progress as an earnest of what will be accomplished in the near future, it leads one to anticipate that within a very short period all the gaps in these tables will be filled in, and new diseases, new disease germs, and new and more reliable methods of diagnosis, prevention, and possibly of treatment be discovered.

In a Huxley lecture the discussion of a biological subject cannot be regarded as inappropriate, even if that subject implies a large amount of what in the present state of knowledge is necessarily of a highly speculative character. Huxley loved a biological problem. He was a great collector of facts, it is true—a great observer; but he tells us his interest in facts was chiefly in as far as they illustrated and led up to principles. In his search for and contemplation of facts, in his endeavour to arrive at principles, he recognised and insisted on the value of hypothesis. In his day, as at the present day, it was the fashion with some to decry and scoff at any hypothesis, however reasonable, that might be advanced in an attempt at explaining or coördinating facts. According to such people the only thing worthy the name of science is *fact*. Huxley, however, was not of this way of thinking. He held that in science hypothesis had a distinct and honourable place, that it was of the greatest value in stimulating and guiding observation and in bringing about discovery. Witness his strenuous advocacy of Darwinism, an advocacy so fully justified by result. Huxley, however, was ever careful to distinguish between hypothesis and fact, and it is in this spirit that I would bring before you some biological problems having important bearings on tropical pathology and possibly on phases of pathology other than tropical, and, also, certain hypotheses which may or may not be verified in the future, but which certainly suggest lines of work which, if pursued, could not fail to elicit new and important facts and perhaps sounder explanations than those I propose to offer.

In the largest and most important section of tropical diseases the germs (I shall take that of malaria as an example) are carried, as I have explained, from human host to human host by animal intermediaries, in this instance an anopheline mosquito. But the malaria mosquito does not function merely as a simple mechanical vector, in the way that the physician's lancet does when it transfers the vaccinia

TABLES OF TROPICAL DISEASES SHOWING OUR PRESENT KNOWLEDGE OF THEIR ETIOLOGY AND MEANS OF PROPAGATION.

TABLE I.—*Diseases Due to Vegetable Parasites.*

Name of disease.	Causative agent.	Mode of transmission.
Diseases due to bacteria—		
Malta fever.	*Micrococcus melitensis* (Hughes, 1893).	May be conveyed in milk from infected animals (goats, cows), also possibly mosquitoes.
Plague.	*Bacillus pestis.*	Inoculation by fleas—contaminated food.
Leprosy.	,, *lepræ.*	Unknown.
Dysentery (bacillary form).	,, *dysenteriæ.*	Contaminated food or water. Flies (especially *Musca domestica*) play an important rôle in the dissemination of these diseases.
Typhoid fever.	,, *typhosus.*	
Cholera.	*Vibrio comma* (Schroter, 1886).	
Diseases due to fungi—		
Mycetoma. Actinomycotic mycetoma.	*Discomyces bovis* (Harz, 1877).	Probably inoculated through the skin by contaminated plant thorns or spikelets.
Vincent's white ,,	,, *maduræ* (Vincent, 1894).	
Nicolle's ,, ,,	*Aspergillus nidulans* (Eidam, 1883).	
Bouffard's black ,,	,, *bouffardi* Brumpt, 1906.	
Classic ,, ,,	*Madurella mycetomi* (Laveran, 1902).	
Brumpt's white ,,	*Indiella mansoni* Brumpt, 1906.	
Bouffard's ,, ,,	,, *somaliensis* Brumpt, 1906.	
Ringworm. Tinea imbricata.	*Trichophyton concentricum* R. Blanchard, 1895.	
,, albigena.	,, *albiscicans* Niewenhuis, 1908.	
,, alba.	,, *macfadieni* (Castellani, 1908).	
,, cruris.	,, *cruris* Castellani, 1905.	
,, sabouraudi.	,, *blanchardi* Castellani, 1905.	
,, nigro-circinata	,, *ceylonense* Castellani, 1903.	
,, intersecta.	,, *castellanii* Perry, 1907.	
,, flava.	*Malassezia tropica* Castellani, 1908.	
,, nigra.	*Foxia mansoni* Castellani, 1908.	
Pinta.	Various as yet undetermined species of *Aspergillus, Penicillium, Monilia*, and *Montoyella.*	
Piedra.	*Trichosporum giganteum* Behrend, 1890.	
Other tropical forms of nodular trichomycosis.	,, *krusei* (Castellani, 1903). ,, *foxi* Castellani, 1903.	
Tropical blastomycoses.	*Saccharomyces cantliei* Castellani, 1903. ,, *samboni* Castellani, 1903. *Cryptococcus louri* Castellani, 1908.	
Tropical sporotrichosis.	*Sporotrichum indicum* Castellani, 1903.	
Erythrasma.	*Discomyces minutissimus* (Burchardt, 1859).	
Pityriasis versicolor.	*Malassezia furfur* (Ch. Robin, 1853).	
Aspergillosis of hairy parts.	*Aspergillus barbæ* Castellani, 1908.	
Penicillosis of hairy parts.	*Penicillium barbæ* Castellani, 1903.	

have it in Ontario, and referred particularly to the outbreak in Hamilton where there had been 80 cases, with a cost to the municipality of $10,000. In nearly every case there had not been any vaccination at all, although there are stringent laws in Ontario compelling vaccination in all over three months of age. He considered that the people were becoming careless and were neglecting vaccination now that the ravages of the disease were becoming less. Too many physicians also were careless in establishing a quarantine in mild cases of the disease. Dr. Evans, medical health officer, Chicago, advised that a committee should be appointed to prepare counter-arguments to the antivaccinationists and to secure the proper dissemination of those arguments.

A report of the Committee on Ophthalmia Neonatorum by Dr. F. Park Lews, chairman, Buffalo, N.Y., brought [illegible] from the speaker that a majority of the cases of ne[illegible] blindness was due to affections of the eyes in infancy. [illegible] test made of ten schools, representing eight States and Ontario, showed that 25 per cent. of those first admitted to the schools were needlessly blind. It was found to be more prevalent in the poorer classes. Referring to the treatment of the eyes of the newly born Dr. Lews stated that silver nitrate in 1 or 2 per cent. solutions within the first [illegible] hours was one of the applications found to be very beneficial. In the United States circulars are spread broadcast regarding the treatment of children's eyes at birth by those most closely associated with the blind. The committee recommended that the public health officials should do all possible to spread knowledge on the subject; that all midwives should be examined and registered; that proper records should be kept in all maternity hospitals of the number of cases of ophthalmia; and that proper legislation in aid of the work should be secured.

Pollution of the Great Lakes and Rivers was dealt with by Dr. J. A. Amyot of Toronto, bacteriologist to the Ontario Board of Health. This great water system consists of Lakes Superior, Huron, Michigan, Erie, and Ontario, with their connecting rivers and straits, comprising an area of 98,640 square miles. Their elevation above sea-level varied from 247 feet (Lake Ontario) to 600 feet (Lake Superior). The depths of these averaged from 120 feet (Lake Erie) to 900 feet (Lakes Huron and Superior). Over 4,000,000 now use this source for their water-supply. The turbidity of this water was generally not more than 2 parts per 1,000,000 except in Lake Erie, where it was from 20 to 25 parts per 1,000,000. In the open lakes miles out the bacterial count seldom exceeded ten per cubic centimetre and did not contain colon bacilli, though the sewerage of over 4,000,000 people was discharged into it. If the water intakes were out 10 or 12 miles from the shore the water would be almost bacteria-free and certainly sewage-free. The normal temperature of this water in the summer time is rarely over 40° F. except on the surface. Referring to Chicago, the largest city on these great lakes, when that city drew its water-supply from the intakes a mile from shore its typhoid fever rate for the last three years of this condition was 115 per 100,000. With the intakes four miles out the rate was reduced to 40 per 100,000. Diverting three-quarters of the sewage reduced the rate to 22 per 100,000. Toronto was then referred to. Toronto this year has voted $3,700,000 for the disposal of its sewage and filtration of its Lake Ontario water-supply. The conclusions drawn by the different speakers in discussing this able paper were that the water-supply of the great lakes was perfect, that it was free from turbidity, and sufficiently hard to use in lead pipes safely.

A paper on the State control of water-supply was contributed by the secretary, Dr. C. O. Probst, who is also secretary of the Ohio State Board of Health. He said that it should be the duty of the State to protect so far as possible from pollution the water-supply. In his opinion this can much better be handled by the board of health than by a special commission. No municipality, corporation, or person should be permitted to place anything of an injurious character into any stream or body of water that is being used for a public water-supply without the approval of the State Board of Health and that board should have a sufficient number of inspectors to keep all sources of supply under close supervision.

On the last day the following papers attracted a great deal of attention: Typhoid in the West, by Dr. S. J. S. Pierce, Winnipeg; A Study of Typhoid Fever in Richmond, Va., U.S.A., by Dr. Ernest Levy and Dr. Allen W. Freeman, Richmond, Va.; Typhoid in Winnipeg, by Dr. R. M. Simpson and Dr. A. J. Douglas, Winnipeg. The facts brought out in Dr. Pierce's paper are collected from a single hospital, the Winnipeg General Hospital, which was incorporated in 1875 with 40 beds. To-day it has over 300 beds. It has received 35,000 patients, of whom 4800 were suffering from typhoid fever, 3500 coming from the city of Winnipeg alone. Out of 4605 case reports examined 3530 were males and 1075 were females. The average of the males was 26 years and of the females 21 years. One-fourth of all the cases in the year occurred in the month of September. The average duration of the fever in 628 cases was found to be 28 days. In 26 years out of the 4605 cases examined there have been 573 deaths. The mortality was high in 1884, when it was 28 per cent. For the past three years it has been 10 per cent. The greatest number of deaths occurred on the eighth day in the hospital and the average entrance was on the ninth day of the disease, the deaths occurring about the end of the second week. Dr. Simpson and Dr. Douglas stated that since 1872 typhoid fever had never been absent from Winnipeg. In 1881 and 1882 occurred the first celebrated boom of Winnipeg and typhoid fever then flourished with great vigour. Another boom came along in 1902 and 1903 and again the disease became rampant. In three years the population doubled. In 1902 there were 356 cases; 1903, 489; 1904, 1275; 1905, 1906; 1906, 1174; and 1907, 307. In spite of the fact that the water-supply was above suspicion—from artesian wells—the typhoid fever rate in Winnipeg presented the somewhat anomalous picture of a city with a pure water-supply and a high typhoid fever rate. The result was a war on privy pits and box closets in those streets not connected with the sewers, and these have been rapidly reduced and in a short time will be completely abolished. This year to Sept. 1st there have only been 160 cases of typhoid fever in Winnipeg. Richmond, Virginia, U.S.A., was selected for the place of meeting in 1909 with the following officers: President, Dr. Gardner T. Swartz, Providence, R.I.; First Vice-President, Dr. R. M. Simpson, Winnipeg; Second Vice-President, Dr. J. Chico, Mexico City; Third Vice-President, Major C. S. Mason, U.S. Army; Secretary, Dr. C. O. Probst, Columbus, Ohio; and Treasurer, Dr. Frank W. Wright, New Haven, Conn.

Sept. 5th.

NOTES FROM INDIA.

(FROM OUR OWN CORRESPONDENTS.)

The Principal Medical Officer in India.

Surgeon-General F. W. Trevor, Principal Medical Officer, His Majesty's Forces in India, proceeded on a tour of inspection from August 14th to 24th, visiting Kasauli, Rawalpindi, and Murree.

Civil Surgeons in the Punjab.

On the motion of the Inspector-General of Civil Hospitals, Punjab, it has been decided by the Punjab Government that commissioned Indian Medical Service officers should on first joining the province for civil employment be attached to the Mayo Hospital, Lahore, or other large civil hospital, for two or three months, for the purpose of acquainting themselves, under proper guidance, with the treatment of a variety of diseases, and more especially of witnessing a considerable amount of operative surgery; and further that such officers, after passing through the Mayo Hospital and before entering on a civil medical charge, should be posted for a month to a district headquarter hospital to enable them to acquire a knowledge of their work as civil surgeons and their collateral duties. The Inspector-General of Civil Hospitals evidently thinks this is a step in the right direction, for it is stated in the press report of the resolution that Indian Medical Service officers having been generally on military duty, which affords but a limited sphere for practice, find themselves inadequately equipped, more especially in regard to operative surgery, when just posted to the civil medical charge of a district where, besides the routine medical work, they have to attend to jail management, sanitary duties, &c. In this assertion all will not be inclined to agree and it is a matter of regret that the Inspector-General should have thought it was necessary to make it, for Indian Medical Service officers in

TABLES OF TROPICAL DISEASES SHOWING OUR PRESENT KNOWLEDGE OF THEIR ETIOLOGY AND MEANS OF PROPAGATION *(Continued).*

TABLE II.—*Diseases Due to Animal Parasites (Continued).*

Name of disease.		Causative agent.	Mode of transmission.
Roundworm infection.	Dracunculosis.	*Dracunculus medinensis* (Linnæus, 1758).	By means of water containing infected cyclops. Possibly actively through the skin.
	Filariasis.	*Filaria bancrofti* (Cobbold, 1877).	Inoculated by mosquitoes.
		,, *loa* (Cobbold, 1864).	Probably inoculated by blood-sucking flies.
		,, *perstans* (Manson, 1891).	*Ornithodoros moubata* and other *argasidæ* (suggested).
		,, *demarquayi* (Manson, 1895).	Unknown.
		,, *volvulus* (Leuckart, 1893).	
		,, *magalhæsi* (Blanchard, 1895).	
		,, *taniguchii* (Penel, 1905).	
		,, *(microfilaria) powelli* (Penel, 1905).	
		,, ,, *philippinensis* (Ashburn and Craig, 1906).	
Tongue-worm infection.		*Porocephalus armillatus* (Wyman, 1848).	Probably by water contaminated by infected pythons.
		,, *moniliformis* (Diesing, 1836).	
Subcutaneous insects.		*Sarcopsylla penetrans* (Linnæus, 1758).	Penetrates actively through the skin.
		Compsomyia macellaria (Fabricius, 1794).	Eggs laid by parent fly on the surface of wounds or in natural openings.
		Dermatobia hominis (Say, 1822).	Probably eggs accidentally swallowed.
		Ochromyia anthropophaga (Em. Blanchard).	
		Cordylobia anthropophaga (Grünberg, 1903).	
		Bengalia depressa (Walker).	

TABLE III.—*Diseases of Unknown Etiology.*

Name of disease.	Causative agent.	Mode of transmission.
Yellow fever.	Probably due to protozoa.	Inoculated by *Stegomyia callopus* and possibly other species.
Blackwater fever.		Possibly inoculated by ticks or other blood-sucking arthropoda.
Typhus fever.		Probably inoculated by *Pediculus corporis* or *cimex lectularius*.
Rocky Mountain spotted fever.		Inoculated by *Dermacentor reticulatus*.
Japanese river fever.		,, ,, a species of *Trombidium* in its larval form.
Pellagra.		Ascribed to the eating of unsound maize.
Beri-beri.	Unknown.	,, ,, ,, rice.
Epidemic dropsy.		Unknown.
Climatic bubo.		
Dengue.	Probably a protozoon.	Inoculated by mosquitoes of the sub-family *Culicinæ*.
Simple continued fever.	Unknown.	Unknown.
Low fever.		
Non-malarial remittent.		
Double continued fever.		
Seven days' fever.		
Three days' fever.		
Hyperpyrexial fever.		
Hill diarrhœa.		
Sprue.		
Infantile biliary cirrhosis.		
Ponos.		
Verruga peruana.		
Chappa.		
Epidemic gangrenous rectitis.		
Ulcerating granuloma of pudenda.	Unknown (Wise has found a spiroschaudinnia; Donovan a saccharomyces).	
Goundou (Anakure).	Unknown.	
Ainhum.		
Onyalai.		
Big heel.		
Tropical phagedæna.		

Permanganate of Potassium and Snake-bite.

The lancet or permanganate of potassium treatment is generally accepted nowadays as the best of many remedies for snake-bite. The annual report of the Sanitary Commissioner of the United Provinces mentions the case of a sub-inspector of police who was bitten by a large cobra on the hand. A friend slit up the wound and rubbed in the permanganate of potassium crystals, and the man declared that he "undoubtedly owed his life to the prompt action taken."

Plague in the United Provinces.

Some interesting statistics concerning plague are given in the latest report of the Sanitary Commissioner of the United Provinces. The mortality from plague in 1907–08 reached the high figure of 328,662 deaths, a total not far short of that recorded in the bad plague year of 1905. Almo[illegible] the distinction of being the only district which did not r[illegible] a single death from this cause, but Jalaun, Banda, Jhan[illegible] Naini Tal, Hamirpur, and Garhwal were also practically free from the disease. Muzaffarnagar, on the other hand, reported no less than 48,859 deaths and a death-rate of 55·70. Only 14 towns out of 106 with a population of 10,000 and upwards were entirely immune, Ganghey (Saharanpur) having the highest death-rate (112·63) and Kairana (Muzaffarnagar) the next (110·65). The report states that the greatest impetus was given to inoculation during the year, great facilities being afforded to anyone who sought this form of protection. The result was that [illegible]4,169 persons were inoculated, against 1846 in 1906. Only eight persons are reported to have died from plague after inoculation, four in Moradabad, two in Bareilly, and one each in the Meerut and Allahabad districts. The four persons at Moradabad were inoculated, it appears, only three or four days before death and were "probably in the inoculation stage of disease."

Sept. 2nd.

AUSTRALIA.

(FROM OUR OWN CORRESPONDENT.)

Melbourne Hospital.

THE sixty-first annual report of this institution is satisfactory, the expenditure only exceeding the income for 1907 by £336. The total number of patients treated was 26,558, including 5333 in-patients. 136 cases of consumption and 168 of cancer were treated during the year. The committee drew attention to the fact that a large proportion of the consumptives were in very advanced stages and the mortality was very excessive. They were undesirable cases in a general hospital and it was hoped that some other provision would be made for them. There are at present 282 beds for consumptives provided by the Government in various institutions. This provision is quite inadequate. A return presented to the committee showed that the number of in-patients contributing to their maintenance for the year ending June 30th, 1908, was as follows: Contributed nothing, 4270; contributed up to 2*s.* 6*d.* per week, 153; contributed up to 5*s.* per week, 320; contributed up to 7*s.* 6*d.* per week, 57; contributed up to 10*s.* per week, 236; contributed up to 15*s.* per week, 55; contributed up to 20*s.* per week, 172; contributed up to 25*s.* per week, 3; and contributed up to 30*s.* per week, 53. No difference is made in the treatment of those who contribute and others. Complaint was recently made at the Alfred Hospital that patients in the paying wards were allowed certain privileges. The secretary has replied that the only difference made in their favour was permission to see visitors every day. This has now been abolished.

Railway Disaster.

After a protracted inquiry the coroner's jury returned a verdict of manslaughter against the engine-drivers of the two engines on the Bendigo express which collided with a stationary train on Easter Monday. A similar verdict was returned against the station master at Braybrook Junction where the accident occurred. Particulars of injuries are now available. 413 claims were lodged, 301 of these being by passengers in the stationary train and 103 from passengers by the express. Four were made by persons standing on the station platform. The claims have been carefully classified and all the claimants examined on behalf of the railway department. The list works out as follows. From shock only, 38 per cent.; bodily injuries, pains, &c., 14 per cent.; insomnia, nervousness, headache, &c., 13 per cent.; spinal injury, 12 per cent.; fractures, 9 per cent.; cuts, bruises, abrasions, 9 per cent.; injuries to head, 4 per cent.; and internal injuries, 1 per cent. 44 persons were killed on the spot or succumbed within a few days. It is estimated that the accident will cost the Victorian Government £250,000.

Proposed Home for Consumptives.

Dr. R. H. J. Fetherston, the health officer of the city of Prahran, a southern industrial suburb of Melbourne, has urged his council to provide a home for advanced cases of consumption amongst the really destitute. The council applied for a block of land for the purpose but local opposition was so strong that the request was refused, notwithstanding that it was supported by Dr. W. P. Norris, the chairman of the Board of Public Health. The opposition was based on the well-known grounds of danger of infection.

Prevention of Consumption.

An important conference of metropolitan municipalities was held at the Collingwood town hall (Melbourne) on June 29th. Upwards of 750 delegates attended, the object being an effort by the Collingwood council to initiate joint action for the provision of accommodation for advanced cases of tuberculosis. Councillor Rain moved:—

> That in the opinion of this conference assembled from the Melbourne and metropolitan municipalities it is necessary that united action should be taken to deal with the scourge of tuberculosis, and that we proceed to discuss the question and to take the best means to act accordingly.

An animated discussion followed in which various difficulties were pointed out, and ultimately it was decided to meet again and, in company with the medical officers of health, to devise a plan of campaign. Dr. Norris, chairman of the Board of Public Health, said there were living in Melbourne year in and year out about 2500 consumptives and of these about 2000 needed some public assistance. In the last few years the mortality from consumption had fallen in Melbourne from 1000 to 600. It might be that 500 advanced cases required beds, and allowing six months for each it would be necessary to provide 250 beds. Sydney had 300 beds for advanced consumptives, and £10,000 or £15,000 were being spent on a new institution. Notification already in force would be the first step towards securing accommodation at an invalid home or a sanatorium.

Tuberculous Cows.

The Perth Central Board of Health has been actively engaged in a crusade against infected milch cows. The department resolved to apply the tuberculin test to dairy herds in the metropolitan area, and a veterinary officer carried out the task. The result has exceeded all expectations. In one dairy 20 out of 726 cows were destroyed, and in another five out of eight were declared unfit to supply milk for human consumption. Altogether in four dairies 41 cows were ordered for destruction. One of the owners affected remarked, "Experts admit that tuberculosis exists in a mild form in most cattle and that the application of the test has the inevitable effect of increasing the temperature. The milk, however, is not affected, and if the Health Department continues its policy of destruction the milk-supply of the metropolis will be seriously threatened."

The Adulteration of Food.

An interesting return has been prepared by the Victorian Board of Public Health of the analyses made under the Pure Foods Act during the past two years. In 1906 953 samples were examined and adulteration was found in 245, the bulk of this being accounted for by samples of adulterated milk. In 1907 the number of examinations rose to 2663, and of these 358 were regarded as below the standards. Milk again contributed most largely to this total. According to this return there is no very appreciable amount of adulteration in the articles analysed, which covered most of the ordinary daily foodstuffs.

Charitable Bequest.

Under the will of the late Mr. Felton an annual sum is distributed to charitable institutions. The awards for 1908 have just been made, the total sum available being £3700. Mr. Felton was the senior partner of Felton, Grimwade, and Co., a well-known firm of wholesale and manufacturing chemists.

Epidemic of Poliomyelitis Acuta.

An epidemic of acute poliomyelitis has been noted during in the laboratory but which in nature are transmitted solely by the insect intermediaries in which they have necessarily undergone sexual changes. The malaria and yellow fever germs have been transmitted artificially many times by blood inoculation from man to man, yet no one can deny that in nature the mosquito is the appropriate transmitter of these germs. Stress has been laid on the fact that in our laboratories the same strain of trypanosomes has been passed from vertebrate to vertebrate through many hundreds of generations and that as yet there has been observed no sign of diminishing vigour or inoculability in the parasites, such as might be interpreted as indicating the approaching necessity for sexual resuscitation. So far as I know, the experiment has not been tried, but I have no doubt the malaria parasite could be similarly transmitted from man to man for many, perhaps hundreds, of generations. It is so transmitted in the same man and that without sexual reinvigoration. Nevertheless we know, unless it is again passed through a mosquito, that it dies out spontaneously in every instance and in a space of time something less than three years. Perhaps if transferred to a fresh blood it would live even longer than this, even without sexual reinvigoration, just as certain amœbæ can be kept alive asexually beyond their natural term by change of culture medium. Some trypanosome infections, including that of sleeping sickness, we know are normally longer lasting than malarial infections; it is reasonable, then, to think that they are proportionately more enduring when transmitted artificially. The argument based on inoculation experiments is, therefore, in my opinion, of little weight.

4. The fourth argument against a general law that blood protozoa requiring arthropod vectors use these vectors as a medium for sexual development is, in my opinion, the most formidable of any hitherto advanced. It is based on the mode in which the virus of the horse disease known as dourine is conveyed. Dourine is a characteristic trypanosome disease. In nature it is contracted during coitus. It can readily be conveyed to other animals, but it affects principally stallions, which convey it to, and, presumably, acquire it from, brood mares. It is conveyed and contracted naturally, therefore, in the same way as syphilis—that is to say, by contact of mucous surfaces. From this it might be inferred that a sexual stage in an insect is unnecessary for this particular trypanosome; and if unnecessary for this trypanosome unnecessary for any species of trypanosome.

Believing in the uniformity of natural operations and in the necessity for sexual reinvigoration in all animals, including the protozoa; and believing that a sexual stage occurs in the case of other trypanosomes, I believe it must occur in that of dourine—*Trypanosoma equiperdum*; and, as with other trypanosomes, that it is passed in some insect as yet unrecognised.

For reasons which I shall presently explain, I conjecture that this insect may be one which itself has acquired parasitic or semi-parasitic habits; and, consequently, seldom passing from horse to horse, is not the usual transmitter of the trypanosome from horse to horse. To compensate for this inefficiency of its sexual medium as a transmitter, the trypanosome by a kind of reversion to ancestral habit, has taken on the habit of contact transmission during its asexual stage, retaining, however, the insect for sexual reinvigoration.

This suggestion will, I daresay, appear to some, probably to most of my hearers, as being so wildly hypothetical as to be scarcely worth considering. But when we come to examine it a little carefully I think we shall find that, after all, it is not without support, or so highly improbable as at first sight it appears to be. Moreover, should it be established, it is conceivable that it might suggest an explanation for some of the many things in epidemiology that are still hard to understand.

That so many parasites require two hosts, a definitive and an intermediary, zoologically so dissimilar as vertebrate and insect or mollusc, has always appeared to me a remarkable phenomenon and one difficult to explain on Darwinian principles. And yet undoubtedly it conforms to these principles. One can readily understand how an animal, originally free, can adapt itself to parasitic life on another animal, but it is very difficult at first sight to explain how it can accustom itself to life in two absolutely different hosts—hosts so far removed from each other zoologically as a man and a mosquito; and, further, that both man and mosquito are essential for its welfare; and, moreover, that in one host—in this case the vertebrate—the parasite has an asexual life and in the other host—the insect—a sexual life. How by any recognised principle of evolution can a life so complicated be attained or explained?

I would with great diffidence and without entering on detail submit the following hypothesis. Vertebrates, arthropods, molluscs, helminths, protozoa have all of them sprung from a common ancestor, or, if not from one common ancestor, from similar ancestors. Very early in the growth of the family tree a certain originally free organism became at first intermittingly, then finally and permanently, parasitic on another organism. In time a definite host and parasite relationship was established between the two. From the original host varieties, species, genera, and so on were gradually evolved. Concurrently with this evolution in the host the parasite, just as its host had done, adapting itself to its changing environment, evolved new varieties, species, genera, &c.

In the course of these concurring evolutionary processes there came a time when, say, the insect and vertebrate strains began to diverge. A certain organism was parasitic on the common insect-vertebrate ancestor. The process of evolution in this host-ancestor being necessarily very gradual, the parasite—as is the case with many existing parasites—was capable of adapting itself to the closely related varieties of the host, among others to the insect-resulting strain and to the vertebrate-resulting strain. Divergence in these host-strains continuing, varieties became species, species genera, and so on, until insect and vertebrate, as they exist at the present day, were evolved.

In the early stages of the evolutionary process the parasite could live in either vertebrate strain or insect strain of host indifferently, but there came a time when it was often more to the advantage of the parasite to pass its sexual life in the ancestral insect strain, its asexual life in the ancestral vertebrate strain. In the process of evolution this at first more or less accidental habit—I can hardly apply the expression "optional habit" to a parasite—became fixed and has been transmitted, so that now the sexual life of the malaria parasite is passed in the mosquito, its asexual life in man.

This is my explanation of the double life, if I may so describe it, of so many and so widely separated parasites, including protozoa, nematodes, trematodes, and cestodes. I can explain it in no other way; the explanation I offer seems to harmonise the facts and to conform to the doctrines of evolution.

In the case of every double-host-using parasite it is obvious that both hosts must be organisms that are in frequent and fairly close association, otherwise the parasite employing them would lack the opportunity of passing from one to the other. Thus it comes about that the parasites of the herbivora are at another stage of their existence parasites of the carnivora; the hydatid of the sheep, the tapeworm of the dog; the trematode of the sheep, the cercaria of the swamp-haunting mollusc; the blood worms of man, the larval nematode of the mosquito. This is obvious; opportunities of passage from host to intermediary, and from intermediary to host, must be of sufficient frequency, otherwise the parasite demanding them would necessarily cease to exist.

At first sight one would think that the more intimate and frequent the association of definitive and intermediary host the better the opportunity for the parasite. Thus one would think that a louse, or an itch insect, or a *Demodex folliculorum*, being permanently in residence on its vertebrate associate, would be a more suitable intermediary for a malaria parasite than the mosquito is. But we know that it is not so, and one of the reasons for this undoubtedly is that these ectozoa comparatively rarely pass from vertebrate to vertebrate; whereas the mosquito is in the habit of biting one man one day, and it may be quite another man a few days later, and so constitutes a most efficient go-between and vector of blood parasites.

But now another principle comes into operation in this complex of parasitism. Insect and vertebrate life have been evolved side by side, springing from a common ancestor. I have endeavoured to explain in what way the parasites they possess in common have been evolved concurrently and along with them, and I have attempted an explanation of the phenomenon of definitive and intermediary host, and to show that this is no fortuitous relationship but a necessary one, and one in entire harmony with the servant. He also gave much of his spare time to mission work in his own neighbourhood. He was a man of ability far greater than the average, with a precise and critical mind which made him a really illuminating diagnostician. He was, moreover, as successful a teacher as he was a skilful surgeon. For these qualities he deserves more credit than is due to mere natural ability, for he developed them under the handicap of a poor physique and ill-health that was almost constant. The circumstances of his fatal illness were almost tragic. In January last whilst at hospital he was attacked with a rapidly ascending spinal paralysis which was apparently of influenzal origin, for no organic lesion of the nervous system was demonstrated after his death. This illness threatened to prove fatal in a few days, but the immediate danger to life subsided, leaving him, however, with a complete paraplegia below the waist. Since then he was "warded" in Westminster Hospital until his death on Sept. 10th. During the eight months of his illness he suffered literal agony from recurrent painful spasms of his legs, and for the last fortnight of his life he had to be kept almost continuously under morphine and chloroform, so that when his end came it was indeed a merciful release. But this makes it none the less to be regretted that such a useful and efficient life should be cut off in the very blossom of its achievement, and the deep sympathies of many are with his relatives and his hospital in their bereavement. [illegible] Paton was a bachelor. Both his parents predeceased him, but he is survived by seven brothers and sisters.

MARY CAROLINE HAMILTON, L.R.C.P. & S. EDIN., L.F.P.S. GLASG.

THE death of Miss Mary Caroline Hamilton, which occurred at Edinburgh on Sept. 7th, after an operation for appendicitis, is announced. The deceased was the daughter of the late Sir Robert Hamilton of Coleherne Court, London. She studied medicine at the Edinburgh School of Medicine, taking her qualifications in 1905. After holding appointments in Edinburgh and Nottingham Miss Hamilton went to St. Agnes and entered into partnership with Miss N. B. Ievers. Miss Hamilton's death is felt as a great loss at St. Agnes where she was a much liked practitioner.

EMILY ELIZABETH EBERLE, M.A., M.B., B.CH., B.A.O. R.U.I., F.R.C.S. IREL.

Dr. Emily Elizabeth Eberle, of 17, Oakfield-road, Clifton, Bristol, died on Sept. 12th at Dublin, where she was staying on a visit. She was the eldest daughter of the late Rev. J. A. Eberle of Dublin and studied medicine at the Royal College of Surgeons in Ireland. She graduated M.A. of the Royal University of Ireland in 1889 and in 1894 obtained the M.B., B.Ch., B.A.O. degrees of the same University; in the latter year Miss Eberle also was admitted F.R.C.S. Irel. Shortly after obtaining her degrees Miss Eberle commenced practice in Clifton. She was for some years a member of the honorary staff of the Royal Hospital for Children and Women, Bristol, the Southwell Maternity Home, and the Read Dispensary. Miss Eberle was highly esteemed in Bristol and Clifton; she was kind and sympathetic and always ready to help any good cause. Much sympathy is felt for her brother (Alderman J. F. Eberle of Bristol) and the family in their breavement.

Medical News.

PRIZES IN BELGIAN UNIVERSITIES.—In the recent annual competitions for honours amongst the medical faculties of Belgium the Ghent students take the best places. Of 17 prizes Ghent carried off ten, Louvain three, Brussels two, and Liége two. One of the Ghent prize-winners was a woman student who graduated as doctor of medicine, surgery, and midwifery two years ago.

THE LATE MR. DAVID DRAFFIN.—Mr. David Kinnear Draffin died at his residence, Nixon Villa, Merthyr Vale (Glamorganshire), on Sept. 14th, in his fifty-third year, after a short illness. Mr Draffin held the qualifications of L.R.C.P. & S. Edin., L.F.P.S. Glasg., and L.R.C.P. & S. Irel. He went to Merthyr Vale about 17 years ago and was medical officer of the Merthyr Vale collieries. He was very highly esteemed in Merthyr Vale and was particularly beloved by the poor to whom he was a true benefactor. During the "strike" in 1898 he did much to alleviate the prevalent suffering. The funeral was largely attended.

CONGRESS OF THE ITALIAN MEDICAL SOCIETY.—The Italian Society of Internal Medicine will hold its eighteenth congress at Rome on Oct. 26th to 29th. The questions for discussion are: (1) The Clinical Significance of Cardiac Arrhythmiæ; (2) Family Neuropathies; and (3) the Consequences of Hyper-alimentation.

THE CARDIFF INFIRMARY.—Colonel Bruce Vaughan, chairman of the house committee of the Cardiff Infirmary, announced at the meeting held on Sept. 16th that an anonymous gift of £10,000 had been received from a Glamorganshire coal owner towards the new wing. An effort is being made to raise an additional income of £7000 per annum, and last May Mr. J. Cory promised to add 25 per cent. to all sums received. In response a Welsh colliery owner sent £1000, Mrs. J. Nixon sent 10,000 guineas, Mr. H. Webb subscribed £3000, and another £1000 was contributed anonymously. The latest gift brings the total to £25,700.

HONG-KONG: PUBLIC HEALTH AND SANITATION, HOSPITALS AND MEDICAL INSTITUTIONS.—According to the report of the Governor, Sir F. J. D. Lugard, K.C.M.G., for the year 1907, considerable progress has been made in rendering existing domestic buildings rat-proof as a preventive of plague. During the year there were 198 deaths from plague, compared with 842 in 1906 and 287 in 1905. There were 1825 deaths from respiratory diseases amongst the Chinese; 655 of these deaths were due to pulmonary tuberculosis, a percentage of 9·6 of the total deaths amongst that community. Beri-beri caused 562 deaths—a high figure. The deaths from malaria were 579, forming an increase on 1906 and 1905, which it is hoped will only be temporary. The average number of deaths from this disease has fallen from 526 in the quinquennium 1898–1902 to 383 in the quinquennium 1903–1907. Military returns of admissions to hospital for malaria show a marked reduction in the incidence of this disease. Government hospitals consist of the Civil Hospital, to which is attached an isolated maternity hospital, the Victoria Hospital for Women and Children, the Kennedy Town Infectious Diseases Hospital, and the hulk *Hygeia* used mainly for the treatment of small-pox. The Civil Hospital contains 150 beds in 19 wards. 2711 in-patients and 17,302 out-patients were treated during the year 1907. 243 cases of malarial fever were admitted, as against 239 in 1906 and 267 in 1905. The maternity hospital contains six beds for Europeans and four for Asiatics. 87 confinements occurred during the year. The Victoria Hospital at the Peak contains 41 beds. During 1907 211 patients were under treatment. Kennedy Town Hospital contains 26 beds. In 1907 63 cases were treated, of which 16 were plague. On the *Hygeia* 167 cases were treated, of which 96 were small-pox. In the lunatic asylum 222 patients of all races were treated during 1907 and there were 13 deaths. The Tung Wah Hospital, opened in 1872, is mainly supported by the voluntary subscriptions of Chinese but receives an annual grant of $8000 from the Government. Only Chinese are treated in this institution which takes the place of a poor-house and hospital for Chinese sick and destitute. Various other services not appertaining to a hospital are performed by the institution, such as the free burial of the poor, the repatriation of destitutes, and the organisation of charitable relief in emergencies. Chinese as well as European methods of treatment are employed in accordance with the wishes expressed by the patients or their friends. About half the number are now treated by Western methods and the number is steadily increasing. The hospital is managed by a committee of Chinese gentlemen annually elected, their appointment being submitted to the Governor for confirmation; it is under the direct charge of a Chinese resident surgeon paid by the Government, and is under the supervision of a visiting physician who is a member of the Medical Department. The Hong-Kong College of Medicine was founded in 1887. 102 students have been enrolled up to the end of 1907 and of these 33 have become qualified licentiates and have obtained various posts under Government and elsewhere.

in the laboratory but which in nature are transmitted solely by the insect intermediaries in which they have necessarily undergone sexual changes. The malaria and yellow fever germs have been transmitted artificially many times by blood inoculation from man to man, yet no one can deny that in nature the mosquito is the appropriate transmitter of these germs. Divergence in these host-strains continuing, varieties became species, species genera, and so on, until insect and vertebrate, as they exist at the present day, were evolved.

In the early stages of the evolutionary process the parasite could live in either vertebrate strain or insect strain of host indifferently, but there came a time when it was often more to the advantage of the parasite to pass its sexual life in the ancestral insect strain, its asexual life in the ancestral vertebrate strain. In the process of evolution this at first more or less accidental habit—I can hardly apply the expression "optional habit" to a parasite—became fixed and has been transmitted, so that now the sexual life of the malaria parasite is passed in the mosquito, its asexual life in man.

This is my explanation of the double life, if I may so describe it, of so many and so widely separated parasites, including protozoa, nematodes, trematodes, and cestodes. I can explain it in no other way; the explanation I offer seems to harmonise the facts and to conform to the doctrines of evolution.

In the case of every double-host-using parasite it is obvious that both hosts must be organisms that are in frequent and fairly close association, otherwise the parasite employing them would lack the opportunity of passing from one to the other. Thus it comes about that the parasites of the herbivora are at another stage of their existence parasites of the carnivora; the hydatid of the sheep, the tapeworm of the dog; the trematode of the sheep, the cercaria of the swamp-haunting mollusc; the blood worms of man, the larval nematode of the mosquito. This is obvious; opportunities of passage from host to intermediary, and from intermediary to host, must be of sufficient frequency, otherwise the parasite demanding them would necessarily cease to exist.

At first sight one would think that the more intimate and frequent the association of definitive and intermediary host the better the opportunity for the parasite. Thus one would think that a louse, or an itch insect, or a *Demodex folliculorum*, being permanently in residence on its vertebrate associate, would be a more suitable intermediary for a malaria parasite than the mosquito is. But we know that it is not so, and one of the reasons for this undoubtedly is that these ectozoa comparatively rarely pass from vertebrate to vertebrate; whereas the mosquito is in the habit of biting one man one day, and it may be quite another man a few days later, and so constitutes a most efficient go-between and vector of blood parasites.

But now another principle comes into operation in this complex of parasitism. Insect and vertebrate life have been evolved side by side, springing from a common ancestor. I have endeavoured to explain in what way the parasites they possess in common have been evolved concurrently and along with them, and I have attempted an explanation of the phenomenon of definitive and intermediary host, and to show that this is no fortuitous relationship but a necessary one, and one in entire harmony with the servant. He also gave much of his spare time to mission work in his own neighbourhood. He was a man of ability far greater than the average, with a precise and critical mind which made him a really illuminating diagnostician. He was, moreover, as successful a teacher as he was a skilful surgeon. For these qualities he deserves more credit than is due to mere natural ability, for he developed them under the handicap of a poor physique and ill-health that was almost constant. The circumstances of his fatal illness were almost tragic. In January last whilst at hospital he was attacked with a rapidly ascending spinal paralysis which was apparently of influenzal origin, for no organic lesion of the nervous system was demonstrated after his death. This illness threatened to prove fatal in a few days, but the immediate danger to life subsided, leaving him, how[illegible] with a complete paraplegia below the waist. Since the[illegible] was "warded" in Westminster Hospital until his death [illegible] Sept. 10th. During the eight months of his illness [illegible] suffered literal agony from recurrent painful spasms of his legs, and for the last fortnight of his life he had to be kept almost continuously under morphine and chlor[illegible], so that when his end came it was indeed a merciful release. But this makes it none the less to be regretted that such a useful and efficient life should be cut off in the ve[illegible] blossom of its achievement, and the deep sympathies of many are with his relatives and his hospital in their bereavement. [illegible] Paton was a bachelor. Both his parents predeceased him, but he is survived by seven brothers and sisters.

MARY CAROLINE HAMILTON, L.R.C.P. & S. EDIN., L.F.P.S. GLASG.

THE death of Miss Mary Caroline Hamilton, which occurred at Edinburgh on Sept. 7th, after an operation for appendicitis, is announced. The deceased was the daughter of the late Sir Robert Hamilton of Coleherne Court, London. She studied medicine at the Edinburgh School of Medicine, taking her qualifications in 1905. After holding appointments in Edinburgh and Nottingham Miss Hamilton went to St. Agnes and entered into partnership with Miss N. B. Ievers. Miss Hamilton's death is felt as a great loss at St. Agnes where she was a much liked practitioner.

EMILY ELIZABETH EBERLE, M.A., M.B., B.CH., B.A.O. R.U.I., F.R.C.S. IREL.

Dr. Emily Elizabeth Eberle, of 17, Oakfield-road, Clifton, Bristol. died on Sept. 12th at Dublin, where she was staying on a visit. She was the eldest daughter of the late Rev. J. A. Eberle of Dublin and studied medicine at the Royal College of Surgeons in Ireland. She graduated M.A. of the Royal University of Ireland in 1889 and in 1894 obtained the M.B., B.Ch., B.A.O. degrees of the same University; in the latter year Miss Eberle also was admitted F.R.C.S. Irel. Shortly after obtaining her degrees Miss Eberle commenced practice in Clifton. She was for some years a member of the honorary staff of the Royal Hospital for Children and Women, Bristol, the Southwell Maternity Home, and the Read Dispensary. Miss Eberle was highly esteemed in Bristol and Clifton; she was kind and sympathetic and always ready to help any good cause. Much sympathy is felt for her brother (Alderman J. F. Eberle of Bristol) and the family in their breavement.

PRIZES IN BELGIAN UNIVERSITIES.—In the recent annual competitions for honours amongst the medical faculties of Belgium the Ghent students take the best places. Of 17 prizes Ghent carried off ten, Louvain three, Brussels two, and Liége two. One of the Ghent prize-winners was a woman student who graduated as doctor of medicine, surgery, and midwifery two years ago.

THE LATE MR. DAVID DRAFFIN.—Mr. David Kinnear Draffin died at his residence, Nixon Villa, Merthyr Vale (Glamorganshire), on Sept. 14th, in his fifty-third year, after a short illness. Mr Draffin held the qualifications of L.R.C.P. & S. Edin., L.F.P.S. Glasg., and L.R.C P. & S. Irel. He went to Merthyr Vale about 17 years ago and was medical officer of the Merthyr Vale collieries. He was very highly esteemed in Merthyr Vale and was particularly beloved by the poor to whom he was a true benefactor. During the "strike" in 1898 he did much to alleviate the prevalent suffering. The funeral was largely attended.

CONGRESS OF THE ITALIAN MEDICAL SOCIETY.—The Italian Society of Internal Medicine will hold its eighteenth congress at Rome on Oct. 26th to 29th. The questions for discussion are: (1) The Clinical Significance of Cardiac Arrhythmiæ; (2) Family Neuropathies; and (3) the Consequences of Hyper-alimentation.

THE CARDIFF INFIRMARY.—Colonel Bruce Vaughan, chairman of the house committee of the Cardiff Infirmary, announced at the meeting held on Sept. 16th that an anonymous gift of £10,000 had been received from a Glamorganshire coal owner towards the new wing. An effort is being made to raise an additional income of £7000 per annum, and last May Mr. J. Cory promised to add 25 per cent. to all sums received. In response a Welsh colliery owner sent £1000, Mrs. J. Nixon sent 10,000 guineas, Mr. H. Webb subscribed £3000, and another £1000 was contributed anonymously. The latest gift brings the total to £25,700.

HONG-KONG: PUBLIC HEALTH AND SANITATION, HOSPITALS AND MEDICAL INSTITUTIONS.—According to the report of the Governor, Sir F. J. D. Lugard, K.C.M.G., for the year 1907, considerable progress has been made in rendering existing domestic buildings rat-proof as a preventive of plague. During the year there were 198 deaths from plague, compared with 842 in 1906 and 287 in 1905. There were 1825 deaths from respiratory diseases amongst the Chinese; 655 of these deaths were due to pulmonary tuberculosis, a percentage of 9·6 of the total deaths amongst that community. Beri-beri caused 562 deaths—a high figure. The deaths from malaria were 579, forming an increase on 1906 and 1905, which it is hoped will only be temporary. The average number of deaths from this disease has fallen from 526 in the quinquennium 1898–1902 to 383 in the quinquennium 1903–1907. Military returns of admissions to hospital for malaria show a marked reduction in the incidence of this disease. Government hospitals consist of the Civil Hospital, to which is attached an isolated maternity hospital, the Victoria Hospital for Women and Children, the Kennedy Town Infectious Diseases Hospital, and the hulk *Hygeia* used mainly for the treatment of small-pox. The Civil Hospital contains 150 beds in 19 wards. 2711 in-patients and 17,302 out-patients were treated during the year 1907. 243 cases of malarial fever were admitted, as against 239 in 1906 and 267 in 1905. The maternity hospital contains six beds for Europeans and four for Asiatics. 87 confinements occurred during the year. The Victoria Hospital at the Peak contains 41 beds. During 1907 211 patients were under treatment. Kennedy Town Hospital contains 26 beds. In 1907 63 cases were treated, of which 16 were plague. On the *Hygeia* 167 cases were treated, of which 96 were small-pox. In the lunatic asylum 222 patients of all races were treated during 1907 and there were 13 deaths. The Tung Wah Hospital, opened in 1872, is mainly supported by the voluntary subscriptions of Chinese but receives an annual grant of $8000 from the Government. Only Chinese are treated in this institution which takes the place of a poor-house and hospital for Chinese sick and destitute. Various other services not appertaining to a hospital are performed by the institution, such as the free burial of the poor, the repatriation of destitutes, and the organisation of charitable relief in emergencies. Chinese as well as European methods of treatment are employed in accordance with the wishes expressed by the patients or their friends. About half the number are now treated by Western methods and the number is steadily increasing. The hospital is managed by a committee of Chinese gentlemen annually elected, their appointment being submitted to the Governor for confirmation; it is under the direct charge of a Chinese resident surgeon paid by the Government, and is under the supervision of a visiting physician who is a member of the Medical Department. The Hong-Kong College of Medicine was founded in 1887. 102 students have been enrolled up to the end of 1907 and of these 33 have become qualified licentiates and have obtained various posts under Government and elsewhere.

In *cancer of the tongue* the division of the lingual gustatory nerve gives the most signal relief from the pain, often otherwise intractable, which is referred to the side of the tongue, to the ear and temple, and indeed to the whole area of the distribution of the third division of the fifth nerve. Ligation of both lingual or both external carotid arteries is followed by subsidence of œdema and diminution of profuse salivation, as well as by cessation of hæmorrhages. Sometimes the mere extraction of the teeth gives great comfort in those cases in which œdema and extensive infiltration of the tongue lead to painful indentations of the organ from pressure against them. It is sometimes not only justifiable but advisable to excise the greater part or the whole of the tongue, even though the whole of the disease cannot be thereby removed. The pain, the putrid odour, and the other most offensive features of the disease are at any rate removed by the operation. Pain often very intense is caused when cystic formations develop rapidly in cancerous glands in the triangles of the neck or beneath the sterno-mastoid muscle. In such cases much relief is quickly given by laying open the swellings and treating the cavity with chloride of zinc pledgets, acetone, a solution of trypsin, or the high-frequency current.

As an instance of the variation of opinion and of practice from time to time as to the limits of the so-called curative operations I may take *cancer of the larynx*.

Opinions have varied greatly and still differ most remarkably with reference to thyrotomy. Since Paul Bruns denounced in 1878 attempts to extirpate cancer of the larynx by means of thyrotomy, and as intralaryngeal operations have been universally abandoned since about 1881, partial and total laryngectomy have been introduced, and in Germany especially are somewhat widely practised. Cases which were formerly considered unfit for operation are now included in the so-called "operable" category. In Germany not only is the entire larynx removed in cases of extrinsic laryngeal cancers, but intrinsic laryngeal cancers, which in England are successfully dealt with by thyrotomy, are submitted to hemi-laryngectomy or total laryngectomy.

Professor Gluck of Berlin, who is a great advocate of total laryngectomy, has performed most extensive operations, including excision of parts of the tongue or parts of the œsophagus, as well as of the cervical lymphatic glands and portions of the nerves of the neck.

In England, on the other hand, Sir Felix Semon and others have given abundant proof of the success of thyrotomy and of the immunity from recurrences which is secured by it in cases of intrinsic cancer of the larynx when diagnosed early and operated upon thoroughly.

Some years ago I performed total laryngectomy on a man who after fully realising what his condition would be for the rest of his life practically committed suicide on the eighth day after the operation. Since this experience I have been strongly adverse to advising any patient to undergo the operation, nor would I again perform it on anyone without previously explaining to the patient in the fullest manner what the post-operative condition must necessarily be and getting from him an answer to the question whether under the circumstances he deemed life would be worth having.

When a patient has refused an operation for the complete removal of the growth, or when the disease and the general condition of the patient do not permit of any such being undertaken, palliative means may give relief. Much improvement often follows tracheotomy when performed in good time. Whenever difficult respiration is threatened tracheotomy should be done without delay, the trachea being opened always low down and as far from the growth as possible.

Gastrostomy is sometimes advised in cases of obstruction caused by the extension of growth on the œsophageal aspect of the cricoid cartilage. In these cases an opening into the stomach may be the only means of palliating the symptoms, because the retention of a tube can rarely be tolerated when the growth intervenes between the rigid cricoid and the resisting spinal column.

A question which might with advantage be discussed at a meeting of the International Society of Surgery is whether gastrostomy is not far too frequently performed in *carcinoma of the œsophagus?* The use of a tube, short or long, should, I venture to think, be more often resorted to than it is. By its means obstruction would be avoided in many cases. Nor are the results of the operation of gastrostomy for œsophageal cancer very satisfactory. This is doubtless in large part due to the late stage in the disease at which the patients will consent to the operation.

One surgeon admits to having done the operation "too late" in half the cases he operated upon. With a 50 per cent. operative mortality all the other patients were believed to have died within six months from the date of the operation. Another surgeon lost one-fifth of his cases from the operation itself; three-fifths died at periods after the operation varying from six weeks to seven months; and of the remaining fifth, all that was known of them was that two out of three were alive at periods of from six weeks to five months after the operation.

That some few patients have been able to swallow semi-solid food, such as custard or bread soaked in milk, for a short time, perhaps even for a few weeks after gastrostomy, cannot with confidence be put down to the credit of the operation. The same thing sometimes occurs independently of gastrostomy. Seelig records a case[2] in which gastrostomy was performed a day or two *after* the ability to swallow had returned, but death took place, nevertheless, eight weeks later after complete inability to swallow had again set in.

In most cases the improvement is of very brief duration. The very cases in which the cessation of efforts at swallowing is most requisite—namely, those in which the separation between the œsophagus and the air passages is very thin—are the most unfavourable for gastrostomy, as these patients invariably die very soon after the operation from perforation into the air passages.

If the prolongation of life for a short period is a matter of moment to the patient, on account of family circumstances, for example, the operation may be desirable in certain cases, but it cannot often be a real advantage to the patient himself.

Concerning gastro-enterostomy for *malignant disease of the stomach*, I am still of opinion that it is very doubtful if sufficient benefit is derived from gastro-jejunostomy or other short-circuiting operations to make it worth while undergoing them. For conditions other than cancer gastro-jejunostomy is undoubtedly often of the highest value, but when undertaken for cancerous affections, even if the patient survives the operation, the prolongation of life is very limited, the ultimate sufferings are in most cases very severe, and the substitute function of the parts concerned is too often unsatisfactory.

Though this view of gastro-jejunostomy for malignant disease of the stomach is not at the present time any more than in 1902 the one generally accepted, there must be many besides myself who, having watched the post-operative phases of these patients, have come to the same conclusion. In many cases I have known, though great relief has for a time been afforded by the operation, still the respite has not seemed to compensate for the subsequent disappointment and misery which preceded death. It has been my lot to watch week after week up to the end patients who have undergone gastro-jejunostomy. Some of them had been regarded for a time as great surgical triumphs. But I have seen these same patients after a brief period of improvement distressed by frequent vomiting, by inability to take food, and by considerable and widespread abdominal pain. And as I watched them in their sad and pitiable plight the question often forced itself upon me whether the postponement of death compensated the patient for the miseries of living or the friends of the patient for the false hopes with which they were buoyed up during the temporary improvement of the invalid.

The immediate mortality from the operation is by no means small. It is probably not far short of from 40 to 45 per cent. If the results in all the cases by all the operators were known, possibly it would be even higher, notwithstanding the small proportion of deaths directly due to the operation itself in the practice of a few specially skilled and experienced operators. It is not, I think, an inhuman thing to say that this high mortality is the least regrettable circumstance connected with the operation.

The morbid changes due to the altered function of the parts after the operation are far from insignificant. Admitting the improvements in operative technique, and the infrequency of certain complications such as obstruction and regurgitation since the very general adoption of the posterior gastro-jejunal junction, there are other troubles arising out of the operation. Severe diarrhœa is often due to the premature servant. He also gave much of his spare time to mission work in his own neighbourhood. He was a man of ability far greater than the average, with a precise and critical mind which made him a really illuminating diagnostician. He was, moreover, as successful a teacher as he was a skilful surgeon. For these qualities he deserves more credit than is due to mere natural ability, for he developed them under the handicap of a poor physique and ill-health that was almost constant. The circumstances of his fatal illness were almost tragic. In January last whilst at hospital he was attacked with a rapidly ascending spinal paralysis which was apparently of influenzal origin, for no organic lesion of the nervous system was demonstrated after his death. The Hong-Kong College of Medicine was founded in 1887. 102 students have been enrolled up to the end of 1907 and of these 33 have become qualified licentiates and have obtained various posts under Government and elsewhere.

metastases. If the mammary gland involved is very large and pendulous, if discharges are profuse or very offensive, or if great pain is localised in the mamma itself then excision is indicated.

In fungating, bleeding, or foully-discharging growths, curetting, followed by the application of the caustics already mentioned in connexion with the palliative treatment of uterine cancer, is often of much benefit. Fell's paste was at one time much used in the Middlesex Hospital, and in my own practice as also in that of some of my colleagues was found to be of great value in such cases.

For the treatment of certain very extreme cases of paralysing œdema and pain of the upper limb I may here refer to what I wrote in 1902 as to the relief afforded by the interscapulo-thoracic amputation of Berger, or amputation through the shoulder-joint, or amputation just below the humeral tuberosities. In two cases in my hospital practice amputation at the shoulder gave very considerable relief. Mr. C. T. Dent of St. George's Hospital performed Berger's operation on account of a recurrent cancerous ulcer in the axilla attended with severe pain and swelling of the limb, and he gives the particulars of three other cases of recurrent carcinoma in which this amputation was done.[12] As Mr. Dent discreetly remarks, "Unless pain were severe, indeed the predominant symptom, the operation would hardly be taken into serious consideration." In the cases in which it has been resorted to great comfort has been derived therefrom.

A very ingenious operation, the definite outcome of work in the cancer research laboratories of the Middlesex Hospital, has quite lately been performed by Mr. W. Sampson Handley for this very disabling complication of breast cancer. The operation, for which Mr. Handley proposes the name of "lymphangioplasty," consists in introducing into the subcutaneous tissue of the swollen arm a number of silk threads running longitudinally upwards from the wrist to terminate in the loose and healthy areolar tissue in or beyond the axilla, and spaced out at convenient intervals around the limb. The treatment is of the nature of drainage by capillary attraction and has been attended by most marked success.[13]

Division of the brachial plexus has been recommended in cases in which there is great pain owing to the brachial nerve trunks being involved but in which the conditions which call for amputation are not present; so also has division or excision of the posterior roots of the spinal nerves in cases of secondary carcinoma of the spinal column. Carcinoma of the vertebræ is always secondary, and almost invariably so to mammary cancer. Sarcoma of the vertebræ is generally secondary, but is sometimes due to direct extension from the overlying structures. When the pain caused by these growths is extreme, the operation of laminectomy, opening of the dura mater, and division or excision of the posterior nerve roots has given great relief.[14]

There is one terrible condition in breast cancer which no operative treatment can relieve, that is cancer *en cuirasse*. I have had several such cases under my care, in some of which nearly the whole of the skin of the chest, abdomen, neck, and shoulders has been involved. The short and difficult breathing, the sensation of continuing suffocation, the pain, and the feeling as if being compressed within a rigid casing form a condition of bodily torture and mental anguish as distressing to witness as anything I have seen. More than one of these patients have expressed themselves to me in almost identically the same words—namely, that they would like to take a large knife and rip themselves open through the chest. The only means I have found of giving relief in these shocking cases has been the administration of liberal doses of spirit of sulphuric ether combined with opium or morphine.

As regards oöphorectomy for mammary cancer, Sir George Beatson has kindly written to me fully as to his present views. These are essentially the same as he held in 1902, since which year he has performed oöphorectomy for mammary cancer in only five cases. He admits that there is no reliable evidence that the operation influences the course of cancer; that as yet no permanent cure has been effected by it; and that "although oöphorectomy has been narrowed down to a comparatively limited group of cases, and although even in the most successful of these no results of a permanent nature have been maintained, yet in view of the very small mortality of the operation *per se* it is a procedure that can be fairly put before the patient as having possible palliative effects that may carry with them improved health and prolonged life."

Of cancer of the *urinary bladder* my later experience tends to confirm the views I expressed in 1902, namely, that excision of the diseased and surrounding parts of the bladder should be the treatment for the cases in which the anterior or upper portion of the organ is affected; and that suprapubic drainage should be employed in other cases where great pain and frequent and painful micturition are present. Dr. Hugh Cabot[15] of Boston recommends curetting and cauterising the growths and temporarily draining through a suprapubic cystotomy opening.

In taking a survey of the treatment of inoperable cancer it is impossible to escape from a feeling of professional remorse at the imperfections in diagnosis and the hesitation and delay in the treatment of precancerous and early cancerous conditions. Whether we think of mammary, of laryngeal, of gastric or rectal cancers, of cancerous disease of the tongue, intestine, or uterus, the conviction is forced upon one that many who are attacked by cancer would have their lives spared altogether and many others would have their lives prolonged and their deaths rendered less painful and sad did the profession at large recognise sooner the threatenings and the early existence of cancer and urge their patients to undergo operation at the earliest possible moment. We have striking object-lessons in cancer of the gall-bladder and of the penis. It is the exception for cancer of the gall-bladder to occur apart from the irritation excited by the presence of gall-stones; it is the exception for epithelioma of the penis to arise apart from the common exciting cause—phimosis. It is estimated that 88 per cent. is the frequency with which primary cancer of the gall-bladder is associated with gall-stones (Courvoisier) and 85 per cent. the frequency with which epithelioma of the penis is associated with phimosis (J. D. Barney). If, then, it was the rule to urge early operation for gall-stones and if circumcision was strongly advised in all cases when the prepuce cannot be easily and completely retracted, but especially when phimosis is present in men past middle life, there can be no doubt that the frequency of cancer in these organs would be diminished. It is almost certain that cholecystotomy has saved many gall-bladders on the verge of becoming cancerous from actually passing into cancer. The rarity of carcinoma following the operation for gall-stones, even though there is gross thickening of the walls of the gall-bladder at the time of the operation, gives countenance to this opinion. On the other hand, the mortality of operations for cancer of the gall-bladder once the disease is established is very high, ranging from 23 to 57 per cent., according to the degree of anæmia, jaundice, and complications from adhesions.

Another typical illustration of a precancerous condition is leucoplakia of the tongue, buccal mucous membrane, and vulva. Although this condition is far from being invariably followed by epithelioma even after existing for many years, it ought to command frequent and careful supervision, and resort should be had to operation at the earliest sign of its transition into cancer. In a paper based on 75 cases of epithelioma and leucoplakia of the tongue which I communicated to the Medical Society of London in 1882,[16] there were 13 cases of leucoplakia associated with cancer, and 14 cases in which the condition had been in existence for periods ranging from eight to 30 years without cancer supervening. This history, together with the fact that the leucoplakic state sometimes returns immediately upon the cicatricial surface, would forbid excision in most of these cases as a precautionary means against cancer, but it should not hinder us from operating on the earliest indication of excoriation or ulceration.

With symptoms of gastric disease continuing unrelieved by medicinal or dietetic treatment, an early exploratory laparotomy will result in the detection in good time of cancer of the stomach and will thus lead to its early removal by

Appointments.

Successful applicants for Vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column, are invited to forward to THE LANCET *Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week, such information for gratuitous publication.*

BERGIN, FRANK GOWER, L.R.C.P. Lond., M.R.C.S., has bee[illegible] and Assistant Skiagraphist at the Bristol General Hospital.

BURNETT, R., M.B., B.S. Vict., has been appointed Medica[illegible] to the Borough of Bury.

CALDWELL, A. G., M.D. R.U.I., has been appointed School M[illegible] Officer for Stockport.

CAPPE, H. N., M.R.C.S., L.R.C.P. Lond., has been appointed [illegible] Medical Officer at the Brookwood Asylum.

GARDEN, DAVID S., M.B., Ch.B., has been appointed Resident Medical Officer at the Aberdeen Royal Infirmary.

JO[illegible] Certifying Surgeon und[illegible] Pontardawe District o[illegible]ty of [illegible]

LLOYD, B., M.B., B.S. Lond., D.P.H. Lond., has been appo[illegible] Assistant Medical Officer of Health and Medical Inspector [illegible] Schools for Newport (Mon.).

MACPHAIL, J. M., M.B., B.S. Edin., has been appoin[illegible] Medical Officer to the Union Hospital, Hope, near Eccles.

MUTERER, JAMES G., M.B., Ch.B., has been appointed Resident Medical Officer at the Aberdeen Royal Infirmary.

TURTON, J. R. H., M.R.C.S., L.R.C.P. Lond., has been appointed Assistant Resident Medical Officer to the London Temperance Hospital.

WELLS, J. DOUGLAS, M.B., Ch.B. Edin., has been appointed Medical Officer to the Billericay Workhouse and Infirmary, and Medical Officer to the District Infectious Hospital of the Billericay Rural District Council.

WILL, JOHN H., M.B., Ch.B., has been appointed Resident Medical Officer at the Aberdeen Royal Infirmary.

Vacancies.

For further information regarding each vacancy reference should be made to the advertisement (see Index).

BIRKENHEAD BOROUGH HOSPITAL.—Junior Resident House Surgeon. Salary £80 and notification fees.

BRIGHTON, SUSSEX COUNTY HOSPITAL.—House Surgeon, unmarried. Salary £120 per annum, with board, residence, and washing. Also Second House Surgeon, unmarried. Salary £80 per annum, with apartments, board, and laundry.

BRISTOL ROYAL INFIRMARY.—Resident Casualty Officer for six months. Salary at rate of £50 per annum, with board, lodging, and washing. Also House Surgeon. Salary £130 per annum, with apartments, board, and laundry. Also Honorary Dental Anæsthetist.

CANCER HOSPITAL, Fulham-road, London, S.W.—Assistant Anæsthetist. Salary 25 guineas per annum.

CENTRAL LONDON THROAT AND EAR HOSPITAL, Gray's Inn-road.—Registrar.

CHESTER COUNTY ASYLUM.—Third Assistant Medical Officer, unmarried. Salary £160 per annum, with board, lodging, and washing.

CITY OF LONDON HOSPITAL FOR DISEASES OF THE CHEST, Victoria Park, E.—House Physicians for six months. Salary at rate of £50 per annum, with board, washing, and residence. Also Resident Medical Officer. Salary £120 per annum, with board, &c. Also Pathologist. Salary 100 guineas per annum.

DREADNOUGHT HOSPITAL, Greenwich.—Two House Physicians and Two House Surgeons for six months. Salary £50 per annum, with board, residence, and washing.

EAST LONDON HOSPITAL FOR CHILDREN AND DISPENSARY FOR WOMEN, Shadwell, E.—House Surgeon for six months. Salary £25, with board, residence, laundry, &c. Also Second Medical Officer for six months. Salary at rate of £40 per annum, with luncheon and tea provided.

GORDON HOSPITAL FOR FISTULA, &c., Vauxhall Bridge-road, S.W.—Anæsthetist.

HAMPSTEAD GENERAL HOSPITAL.—House Physician and House Surgeon, both for six months. Salary at rate of £70 per annum, with board and residence. Also Physician to Out-patients, Surgeon to Out-patients, and Ophthalmic Surgeon to Out-patients.

HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST, Brompton —Resident House Physicians for six months. Salary £25. Also Resident Medical Officer. Salary £200 per annum, with board and residence. Also Assistant Resident Medical Officer. Salary £100 per annum, with board and residence. Also Clinical Assistants for six months. Salary at rate of £100 per annum.

HUDDERSFIELD INFIRMARY.—Junior House Surgeon. Salary £80 per annum, with board, residence, and washing.

HULL AND SCULCOATES DISPENSARY.—Resident Surgeon. Salary £220 per annum, with house, gas, and coals.

HUNTINGDON COUNTY HOSPITAL.—House Surgeon. Salary at rate of £80 per annum, with board, &c.

ISLE OF MAN ASYLUM.—Assistant Medical Officer. Salary £150 per annum, with board, quarters, and washing.

JERSEY GENERAL DISPENSARY AND INFIRMARY.—Resident Medical Officer. Salary £120 per annum.

KING'S LYNN, WEST NORFOLK AND LYNN HOSPITAL.—House Surgeon. Salary £100.

LANCASTER, ROYAL LANCASTER INFIRMARY.—House Surgeon, unmarried. Salary £100 per annum, with residence, board, attendance, and washing.

LEAMINGTON, WARNEFORD, LEAMINGTON, AND SOUTH WARWICKSHIRE GENERAL HOSPITAL.—Two Resident Medical Officers. Salary for Senior £100, and for Junior £65 per annum, with board, washing, and apartments.

LONDON HOSPITAL, Whitechapel, E.—Assistant Surgeon.

MANCHESTER, MONSALL FEVER HOSPITAL.—Third Medical Assistant. Salary £100 per annum, with board, lodgings, and washing.

MANDALAY MUNICIPALITY.—Health Officer. Salary Rs.600 (£40) per mensem.

NORTH SHIELDS, TYNEMOUTH VICTORIA JUBILEE INFIRMARY.—House Surgeon. Salary £100 per annum, with rooms, board, &c.

NORWICH, NORFOLK COUNTY ASYLUM, Thorpe.—Junior Assistant Medical Officer, unmarried. Salary £150 per annum, rising to £200, with board, lodging, washing, and attendance.

OLDHAM INFIRMARY.—Senior House Surgeon. Salary £100 per annum, with board, residence, and washing.

PADDINGTON GREEN CHILDREN'S HOSPITAL, London, W.—House Physician and House Surgeon for six months. Salary at rate of 50 guine[illegible] year, with board and residence. Also Honorary Physician to Ou[illegible]nts.

PENDLEB[illegible] **MANCHESTER CHILDREN'S HOSPITAL.**—Visiting Physician. Honorarium, £100 per annum.

PRESTWICH COUNTY ASYLUM, Manchester.—Junior Assistant Medical Officer, unmarried. Salary £150, increasing to £250, with rations, apartments, and washing.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—Examiner in Physiology. Also Examiner in Dental Surgery.

ROYAL NAVY, MEDICAL DEPARTMENT.—Fifteen Commissions.

SALFORD ROYAL HOSPITAL.—House Surgeon for six months. Salary at rate of £60 per annum, with board and residence.

SAMARITAN FREE HOSPITAL FOR WOMEN, Marylebone-road, N.W.—Clinical Assistants.

SOUTHAMPTON FREE EYE HOSPITAL.—House Surgeon. Salary £100 per annum, with board and residence.

SOUTHWARK UNION INFIRMARY, East Dulwich grove, S.E.—Assistant Medical Officer. Salary £100 per annum, with board, lodging, and washing.

TAUNTON, TAUNTON AND SOMERSET HOSPITAL.—Resident Assistant House Surgeon for six months. Salary at rate of £50 per annum, with board, lodging, and laundry.

TORQUAY, PARISH OF.—Medical Officer. Salary £100 per annum.

VIRGINIA WATER, SURREY, HOLLOWAY SANATORIUM HOSPITAL FOR THE INSANE.—Junior Assistant Medical Officer (female). Salary £150 per annum, rising to £200, with board, lodging, laundry, attendance, &c.

WESTMINSTER HOSPITAL, Broad Sanctuary, S.W.—Fourth Assistant Physician.

WINSLEY, NEAR BATH, THREE COUNTIES SANATORIUM FOR CONSUMPTIVES.—Resident Medical Officer, unmarried. Salary £200, rising to £300.

THE Chief Inspector of Factories, Home Office, S.W., gives notice of a vacancy as Certifying Surgeon under the Factory and Workshop Act at Dervock, in the county of Antrim.

Births, Marriages, and Deaths.

BIRTHS.

CALLENDER.—On Sept. 18th, at Inverard, Sidcup, Kent, the wife of Thomas Marshall Callender, M.D., C.M., F.R.C.S. Edin., of a son.

GEDGE.—On Sept. 20th, at Pewsey, Wilts, the wife of Arthur Sydney Gedge, M.R.C.S., L.R.C.P., of a daughter.

HOULBROOK.—On Sept. 15th, at Bradwell, North Derbyshire, the wife of William E. Houlbrook, M.R.C.S. Eng., L.R.C.P. Lond., of a son.

SPRIGGS.—On Sept. 16th, at Bryanston-street, Portman-square, W., the wife of Edmund Ivens Spriggs, M.D., F.R.C.P., of a daughter.

MARRIAGES.

EVANS—BRIANT.—On Sept. 16th, at Brixton Independent Church, Brixton, S.W., Arthur H. Evans, M.S., F.R.C.S., of Harley-street, to Dorothy, younger daughter of Lawrence Briant, of Loughborough Park.

HIGHET—ROBINOW.—On Sept. 19th, at St. Margaret's Church, Altrincham, Cheshire, by the Vicar, the Rev. Hewlett Johnson, M.A., B.Sc., Hugh Campbell Highet, M.D., D.P.H., Principal Medical Officer, Local Government, Bangkok, Siam, to Emma, daughter of the late Max Robinow of Manchester, and of Mrs. Robinow of Hawthornden, Bowdon, Cheshire.

LUNN—PILDITCH.—On Sept. 16th, at St. Paul's (Church of the Venerable Bede), Jarrow-on-Tyne, by the Rev. J. Anderson-Robertson, B.A. (Oxon.), M.D. (Glasgow), uncle of the bridegroom, assisted by the Rev. C. R. J. Loxley, M.A., Rector of Jarrow, John Lunn, M.B., C.M., W.A.M.S., of Edinburgh, to Florence Gertrude, only daughter of Alfred Pilditch, of Jarrow-on-Tyne, and formerly of Froome-Selwood, Somerset, and Stonehouse, Devon.

WATNEY—CROSSLEY.—On Sept. 16th, at St. Thomas's Church, Belfast, Herbert Andrew Watney, M.B., B.S., son of the late Rev. James Watney, of Canwick, Lincoln, to Olive Emily, second daughter of the late Arthur C. Crossley of Belfast.

DEATHS.

CRANE.—On Sept. 20th, at Warwick-square, S.W., Charles Albert Crane, M.D., aged 65 years.

N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

general recognition. During the bacteriological era in the investigation of cancer, the part ferments play in many complex processes outside of the intestinal canal itself has become more fully recognised. Regarding the intestinal digestive ferments themselves, revolutionary discoveries have been made as the result of investigations by Pawlow, Starling and Bayliss, and others. The study of immunity to the toxins of disease under Ehrlich's leadership directed attention to the fact that the serum of the blood normally possesses a power to neutralise the activity of most and probably of all of the intestinal digestive ferments. French investigators on Metchnikoff's initiative have studied not only the power of leucocytes to digest bacteria, but have shown also that they can digest albumins and that the latter process is effected by a ferment indistinguishable from trypsin. It is certainly remarkable that the white cells of the blood possess the power of tryptic digestion yet circulate in a serum which possesses antitryptic along with its other antifermentative powers.

With so much evidence existing of the part played by ferments in the activity and counter-activity of the cells and fluids of the body, both in the building up and breaking down of tissue, it was natural that the investigation of fermentative action should be extended to the study of the growth of malignant tumours, not only with a view to explain their destructive action on healthy tissues even so difficult to attack as cartilage and bone, but also in the hope of neutralising their pernicious effects. It appeared reasonable that healthy tissues might be protected from the digestive powers of the cancer cell. There was even hope of attacking the cancer cell itself if it were found so to differ in its chemical constitution as to be more vulnerable to the actions of intestinal and other ferments than the other tissues of the body.

The occurrence of specific ferments in cancer has been described (Petri and others), but the first step in the practical application of digestive ferments to the treatment of cancer was made by F. Blumenthal, who adduced evidence that cancerous tissue seemed to be digested by pancreatin more readily than normal tissue. His observations acquired a further significance by other investigations which appeared to show that cancerous tissue was of a chemical constitution different from normal tissue. Blumenthal does not appear actually to have employed trypsin for the treatment of cancer as a result of his experiments *in vitro*. Its therapeutical application was advocated in the first place by Shaw-Mackenzie on the clinical ground that cancer was relatively infrequent in the duodenum, and on the further ground that he had observed the frequent occurrence of diabetes and cancer in different members of the same family. About the same time also it was employed by J. Beard who has formed ideas on the relation of the activity of the pancreas to the development of cancer and asserts that trypsin has a specific action on cancerous as opposed to the normal tissues of the body.

The attention thus directed to trypsin and the contradictory statements of the results which have followed its use, and perhaps also the hurry to find out if there might not be some ferment the employment of which could be heralded as the long-sought panacea free from the difficulties at once met with in the use of trypsin, have led to numerous attempts to apply other ferments. Thus the following have been tried: amylopsin, in addition to trypsin, suggested on embryological grounds (Beard), liver ferment (von Leyden and Bergell), placental tryptic ferment (Bumm, Liepmann), papayotin (Branch, Lucas), and lastly erepsin—which is contained chiefly in the intestinal mucous membrane (Cohnheim) but is common to all organs and tissues (Vernon)—has been recommended and is being experimented with by Shaw-Mackenzie.

Only in regard to the use of trypsin has sufficient time elapsed for any number of cases to be reported, and since it can scarcely have been extensively applied for more than two years, the intervals since treatment was commenced hardly justify drawing definite conclusions from clinical data alone as to what the ultimate effects of its application may be. The statements which have precipitately followed one another during the past year or more have been very contradictory and some, unfortunately, too controversial for consideration here. While of some cases statements obviously too sanguine have been made, in others the treatment appears to have relieved pain and benefited the patients at least for a time, at the cost of nothing more than a slight malaise. Other observers report complete failure to relieve the patients of any of their symptoms. The treatment has been described to be painful, to be liable to induce toxæmia, even coma and death, and to produce sterile abscesses at the site of inoculation.

Dr. J. A. Shaw-Mackenzie who, as the first to apply trypsin practically, has probably the longest experience of its effects, has latterly taken up the position that the hope that trypsin would reach the site of the disease through the blood stream when injected at a distance "does not accord with the view generally admitted that the blood possesses certain antitryptic properties"; and that "the local atrophy and degeneration of a cancerous growth induced by subcutaneous injections of trypsin in the neighbourhood of a tumour or into the substance of the tumour itself cannot be accepted as evidence of the successful treatment of cancer." He also states that "the extreme amount of physical suffering has been the invariable result" of direct injection into the tumour or into its periphery.

In contrast with this dispassionate statement on the part of one whose interests in the ferment treatment of cancer have every appearance of sincerity must be placed numerous less balanced statements made by participants in the controversy which has been waged as to whether trypsin was of any use whatsoever. In America, Rice, Morton, Margaret Cleaves, Luther, and others have reported most favourable results in the treatment of the primary and secondary growths of a large number of cases of carcinoma and sarcoma. Bainbridge of New York has severely criticised the use Morton made of the data referring to a case of carcinoma of the breast which, as published by Morton, seemed to afford the most convincing evidence of cure.

In England success has been reported by Dr. Charles C. Scott, Dr. C. T. Hilton, Mr. O. H. Hudson, Dr. T. F. Cavanagh, Mr. H. Meggitt, and others, but lapse of time does not warrant the conclusion from the relief afforded that cures have been obtained. Investigators at the Middlesex Hospital and the London Hospital and at the Brompton Cancer Hospital have stated their failure to obtain satisfactory results similar to those recorded by some private practitioners. Dr. E. F. Bashford after testing the action of trypsin on the growth of tumours in mice has stated categorically that it is devoid of any influence. Mr. A. Carless has dissented from the deductions favourable to trypsin which have been drawn from Dr. Scott's case of apparent carcinoma of the large intestine. Dr. J. Alcindor has recorded one case of new growth in the iliac fossa and a case of carcinoma mammæ, in both of which untoward symptoms, combined with some apparent relief to the patients, accompanied treatment with trypsin during the last months of life. It appears very probable that only a very small proportion of the cases which have been treated with trypsin in England have as yet found their way into print, owing to the desire to await evidence that any benefit conferred will persist; but this paucity of reports is undoubtedly also due to the large proportion of cases in which no benefit has resulted or in which treatment has not been persisted in owing to the pain caused and the risk of undesirable complications.

In Germany the treatment of cancer by trypsin has aroused attention owing to the noisy prominence given to it in the lay and medical press in England and America. Von Leyden and Bergell, Gellhorn, and Bumm have stated that it has no practical value. Schöne summarises the whole question as follows: "As it is well known Beard recommended the use of trypsin for the treatment of malignant new growths, and more recently as the result of no less fantastic considerations which likewise will not bear searching examination, he has recommended the use of amylopsin. In spite of much competent investigation it is only possible to state that convincing successes are apparently absent." A. Pinkus, Kuhn, and Blumenthal have suspended their judgment on the value of the treatment. Blumenthal and A. Pinkus in reply to inquiry have protested against the misuse of their statements in support of the extravagant claims made for trypsin in England.

With rare exceptions trypsin has been applied by hypodermic injections. In some cases, however, it has been administered by the mouth or as a local application, and as regards the external use there is greater uniformity in the statements of results. Sloughing tissue is speedily removed, as was to be expected, and a clean surface free from sepsis

OPERATIONS.

METROPOLITAN HOSPITALS.

MONDAY (28th).—London (2 P.M.), St. Bartholomew's (1 30 P.M.), St. Thomas's (3.30 P.M.), St. George's (2 P.M.), St. Mary's (2.30 P.M.), Middlesex (1.30 P.M.), Westminster (2 P.M.), Chelsea (2 P.M.), Samaritan (Gynæcological, by Physicians, 2 P.M.), Soho-square (2 P.M.), City Orthopædic (4 P.M.), Gt. Northern Central (2.30 P.M.), West London (2.30 P.M.), London Throat (9 30 A.M.), Royal Free (2 P.M.), Guy's (1 30 P.M.), Children, Gt. Ormond-street (9 A.M.), St. Mark's (2.30 P.M.).

TUESDAY (29th).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), Guy's (1.30 P.M.), Middlesex (1.30 P.M.), Westminster (2 P.M.), West London (2.30 P.M.), University College (2 P.M.), St. George's (1 P.M.), St. Mary's (1 P.M.), St. Mark's (2.30 P.M.), Cancer (2 P.M.), Metropolitan (2.30 P.M.), London Throat (9.30 A.M.), Samaritan (9.30 A.M. and 2.30 P.M.), Throat, Golden-square (9.30 A.M.), Soho-square (2 P.M.), Chelsea (2 P.M.), Central London Throat and Ear (2 P.M.), Children, Gt. Ormond-street (9 A.M. and 2 P.M.), Ophthalmic (2 P.M.), Tottenham (2.30 P.M.).

WEDNESDAY (30th).—St. Bartholomew's (1.30 P.M.), University College (2 P.M.), Royal Free (2 P.M.), Middlesex (1 30 P.M.), Charing Cross (3 P.M.), St. Thomas's (2 P.M.), London (2 P.M.), King's College (2 P.M.), St. George's (Ophthalmic, 1 P.M.), St. Mary's (2 P.M.), National Orthopædic (10 A.M.), St. Peter's (2 P.M.), Samaritan (9 30 A.M. and 2 30 P.M.), Gt. Northern Central (2.30 P.M.), Westminster (2 P.M.), Metropolitan (2.30 P.M.), London Throat (9.30 A.M.), Cancer (2 P.M.), Throat, Golden-square (9 30 A.M.), Guy's (1.30 P.M.), Royal Ear (2 P.M.), Royal Orthopædic (3 P.M.), Children, Gt. Ormond-street (9 A.M. and 9 30 A.M., Dental, 2 P.M.), Tottenham (Ophthalmic, 2.30 P.M.), West London (2.30 P.M.).

THURSDAY (1st).—St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), University College (2 P.M.), Charing Cross (3 P.M.), St. George's (1 P.M.), London (2 P.M.), King's College (2 P.M.), Middlesex (1.30 P.M.), St. Mary's (2.30 P.M.), Soho-square (2 P.M.), North-West London (2 P.M.), Gt. Northern Central (Gynæcological, 2.30 P.M.), Metropolitan (2.30 P.M.), London Throat (9 30 A.M.), Samaritan (9.30 A.M. and 2.30 P.M.), Throat, Golden-square (9.30 A.M.), Guy's (1.30 P.M.), Royal Orthopædic (9 A.M.), Royal Ear (2 P.M.), Children, Gt. Ormond-street (9 A.M. and 2 P.M.), Tottenham (Gynæcological, 2.30 P.M.), West London (2.30 P.M.).

FRIDAY (2nd).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), Guy's (1.30 P.M.), Middlesex (1.30 P.M.), Charing Cross (3 P.M.), St. George's (1 P.M.), King's College (2 P.M.), St. Mary's (2 P.M.), Ophthalmic (10 A.M.), Cancer (2 P.M.), Chelsea (2 P.M.), Gt. Northern Central (2.30 P.M.), West London (2.30 P.M.), London Throat (9.30 A.M.), Samaritan (9.30 A.M. and 2.30 P.M.), Throat, Golden-square (9.30 A.M.), City Orthopædic (2.30 P.M.), Soho-square (2 P.M.), *Central London* Throat and Ear (2 P.M.), *Children*, Gt. Ormond-street (9 A.M., Aural, 2 P.M.), Tottenham (2.30 P.M.), St. Peter's (2 P.M.).

SATURDAY (3rd).—Royal Free (9 A.M.), London (2 P.M.), Middlesex (1.30 P.M.), St. Thomas's (2 P.M.), University College (9.15 A.M.), Charing Cross (2 P.M.), St. George's (1 P.M.), St. Mary's (10 A.M.), Throat, Golden-square (9.30 A.M.), Guy's (1.30 P.M.), Children, Gt. Ormond-street (9 A.M. and 9.30 A.M.), West London (2.30 P.M.).

At the Royal Eye Hospital (2 P.M.), the Royal London Ophthalmic (10 A.M.), the Royal Westminster Ophthalmic (1.30 P.M.), and the Central London Ophthalmic Hospitals operations are performed daily

EDITORIAL NOTICES.

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITOR," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention should be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this office.

Lectures, original articles, and reports should be written on one side of the paper only, AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers—not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale and advertising departments of THE LANCET *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

MANAGER'S NOTICES.

TO SUBSCRIBERS.

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, London, W.C., are dealt with by them? Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid, and *not* to THE LANCET Offices.

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will insure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

THE COLONIAL AND FOREIGN EDITION (printed on thin paper) is published in time to catch the weekly Friday mails to all parts of the world.

The rates of subscriptions, post free, *either* from THE LANCET Offices or from Agents, are:—

FOR THE UNITED KINGDOM.		TO THE COLONIES AND ABROAD.	
One Year	£1 12 6	One Year	£1 14 8
Six Months	0 16 3	Six Months	0 17 4
Three Months	0 8 2	Three Months	0 8 8

Subscriptions (which may commence at any time) are payable in advance. Cheques and Post Office Orders (crossed "London and Westminster Bank, Westminster Branch") should be made payable to the Manager, Mr. CHARLES GOOD, THE LANCET Offices, 423, Strand, London, W.C.

TO COLONIAL AND FOREIGN SUBSCRIBERS.

SUBSCRIBERS ABROAD ARE PARTICULARLY REQUESTED TO NOTE THE RATES OF SUBSCRIPTIONS GIVEN ABOVE. It has come to the knowledge of the Manager that in some cases higher rates are being charged, on the plea that the heavy weight of THE LANCET necessitates additional postage above the ordinary rate allowed for in the *terms of* subscriptions. Any demand for increased rates, on this or on any other ground, should be resisted. The Proprietors of THE LANCET have for many years paid, and continue to pay, the whole of the heavy cost of postage on overweight foreign issues; and Agents are authorised to collect, and generally do so collect, from the Proprietors the cost of such extra postage.

was adopted by gynæcologists throughout the world was a fair measure of the universal, though not audibly expressed, dissatisfaction with the usual mechanical treatment of displacements of the uterus. We may also now consider the number and variety of the recent modifications of Alexander's operation as a fair indication of the disappointment of operators who have applied it without sufficient discrimination as to its limitations. For my own part, after operating in 45 cases I abandoned the method of treatment altogether as the result of certain experiences to detail which would be too much of a digression. My troubles suggested to my mind serious objections to the operation in private practice owing to an element of uncertainty as to the possibility of its satisfactory completion. When completed in a perfectly correct manner it did not seem to me to stand well the test of pregnancy and parturition.

The modifications of Alexander's operation which have been most pressed upon the attention of gynæcologists appear to have all the weaknesses of the original operation, or to be more extensive and presumably more dangerous than ventrifixation. This objection attaches, for example, to the proceeding of opening the vagina behind the uterus in order to break down adhesions before dealing with the round ligaments themselves. And the objection on account of its formidable character applies, for example, to Goldspohn's modification, which involves all the details of abdominal section with two wounds instead of one, as in ventrifixation. He refers to it himself as "this bilateral inguinal cœliotomy and shortening of the round ligaments viâ the dilated inguinal rings." He also remarks: "It has become very clear that the simple Alexander operation without this interperitoneal work is generally too imperfect and imbecile a procedure ......" But his own modification is the operation which Goldspohr declares to be among "the most rational, innocent, and effective methods in the treatment of pathologic retroversions and retroversio-flexions of the uterus." Another American gynæcologist claims for his own modification all these advantages and that in addition it is "the most esthetic," whatever that term may mean under the circumstances.

The staggering array of modifications involving hooking and turning and twisting of the round ligaments from a wound in the vagina either in front of or behind the uterus, or by means of more or less formidable wounds in the inguinal regions, seem hardly worthy of serious attention except with the object of appraising their value and utterly condemning and rejecting them. They are at the best blind and uncertain.

The operation of ventrifixation efficiently done appears to me to be the best for the treatment of chronic retroflexion of the uterus in women at the child-bearing time of life. It was first suggested, I believe, by Olshausen in 1886, when he fixed the cornua of the uterus very slightly as an afterthought incident in an operation undertaken owing to other indications than backward displacement. The operation has been much practised with a defective technique in Germany, but, what implies a great deal in its favour, it has been taken up in France and practised on its merits, although originating in Germany.

My first operation was performed in September, 1890, and I gradually evolved a method of operating which has fulfilled all my hopes and expectations. As an operation of choice it had rigidly to comply with certain requirements or to stand condemned on its demerits. It does not seem to me to deserve condemnation: much the contrary. The tests which such an operation must stand appeared to me to be: (1) it must be devoid of danger when ordinary care is exercised; (2) it should be easy to perform, and the operator must feel certain in recommending it to a patient that he can undertake it with absolute certainty of being able to finish it as planned; (3) it must relieve the symptoms on account of which it was undertaken; (4) it must not produce any new symptoms that will even remind the patient for any considerable time that she has undergone an operation; (5) it must leave the patient free from any remote danger such as ileus, and permanently in a condition for active exertion and for all the duties of life indistinguishable from her original normal state of health; (6) it must stand the strain of pregnancy and parturition and the puerperium without abnormal distress, as if the operation had never been done; and (7) the uterus must continue after involution to maintain the position it was placed in by the operation. An operation which complies with all these conditions has many merits whatever *a priori* objections may be raised by preconception or prejudice, or whatever may be the terms employed to condemn justly an operation labelled "ventrifixation" by those who have met with the unfortunate experiences which were only to be expected from defective and irrational methods of operating.

In order to obtain the desired results certain principles must be kept in mind and complied with in every case. In the first place, the fundus uteri and the round ligaments must be strictly safeguarded, so that if pregnancy occurs it may run a perfectly normal course, as if "fixation" had not been produced. Another important object is to effect complete and permanent adhesion of a sufficient area of the *anterior* surface of the uterus to the abdominal wall. The ideal ventrifixation is that which results from Cæsarean section when the wound is longitudinal, involving about the middle third of the uterus, and extensive and complete and symmetrical adhesion takes place between the uterine and abdominal wounds. In these cases when pregnancy occurs again, as I have known it to do repeatedly, there are absolutely no abnormal symptoms, either functional or mechanical, resulting from the adhesion, and the operation may be repeated almost or altogether without opening the peritoneum. I have only once had occasion to open the abdomen in a patient who had undergone ventrifixation in the manner which I am advocating, and I took the opportunity of examining the relations of the uterus to the abdominal wall. The uterus appeared to be completely incorporated with the anterior parietes in its middle third, and yet the patient had never experienced any unpleasant symptom referable to the uterus or bladder during the several years that had elapsed since the operation. If this can be true in one case why not in all? We cannot avoid adhesions of bowel or omentum after an intra-abdominal operation producing a wound; we should therefore try to make the adhesions strong, regular, and useful instead of leaving them for chance to make them weak, irregular, and dangerous. Firm and broad attachment is not in itself troublesome or dangerous. The *a priori objection to firm* and permanent adhesion is opposed to all the lessons of experience.

Before going into the details of the operation let us consider what we should avoid. We can, perhaps, best do this by looking at the descriptions of the operation of ventrifixation or ventrisuspension in some of the manuals and text-books which beginners in abdominal surgery naturally consult for guidance, and by tracing the course of post-operation pregnancy and labour. Dr. Howard A. Kelly's method of operating has been much followed by gynæcologists abroad and to some extent in this country, but it is extremely faulty in several respects. The introduction of sutures "through the posterior surface of the uterus" should be in itself sufficient to condemn it. In what respect is it better than vaginofixation, the most dangerous and worst of all the important operations practised on women at the child-bearing time of life? Kelly's operation appears to be suspension of the uterus, not fixation; and to the extent to which it fails owing to stretching of the adhesions it benefits the patient only by relieving the fundus from its misplaced attachment, while it adds to her danger from ileus. No wonder that a large proportion of the patients operated upon according to Kelly's method who became pregnant experienced suffering from abnormalities calling for even Cæsarean section. But suspension injuriously affects all cases whether pregnancy occurs or not. It causes dragging upwards of the uterus instead of supporting it and makes it into an atonic pouch, with resulting menstrual anomalies and troubles and persistent intermenstrual discomfort.

When pregnancy does occur after ventrifixation or suspension the consequences may be very serious. Dr. Craigin[2] of New York in a recent article says: "Including the five cases reported in this paper there are now at least 40 cases of Cæsarean section on record which were demanded by a previous ventrifixation of the uterus." Dr. Polak of Brooklyn in a surgical thesis read before the American Gynæcological Society in 1908, entitled "A Report of 52 Pregnancies and Labours following Ventrisuspension of the Uterus for Retro-displacements," quotes from Kelly on the complications in pregnancy and labour which may follow ventrifixation. It should be kept in mind that Dr. Polak sets out *parti pris* as advocate of what he calls ventrisuspension as opposed to

The Huxley Lecture

ON

RECENT ADVANCES IN SCIENCE AND THEIR BEARING ON MEDICINE AND SURGERY.

Delivered at Charing Cross Hospital on Oct. 1st, 1908,

BY SIR PATRICK MANSON, M.D. ABERD.,
F.R.C.P. LOND., K.C.M.G., F.R.S.,
LECTURER ON TROPICAL DISEASES AT ST. GEORGE'S HOSPITAL AND
CHARING CROSS HOSPITAL MEDICAL SCHOOLS AND AT
THE LONDON SCHOOL OF TROPICAL
MEDICINE.

MR. PRESIDENT AND GENTLEMEN,—In preparing the following remarks I have assumed that the council of Charing Cross Hospital Medical School have asked me to deliver this the seventh biennial Huxley lecture because they are impressed by the position attained by tropical medicine in recent years and because they know I have given some attention to the subject. I appreciate and am grateful for the compliment implied, although I fear I can do only scant justice in the short time at my disposal to what has become a large and important subject.

All must recognise that tropical medicine is a theme specially appropriate for a Huxley lecture, seeing that tropical medicine, so far as the etiology and prophylaxis of tropical disease are concerned, is in great measure a branch or development of one of those sciences so intimately associated with Huxley's name—*natural* history. Moreover, the success with which the study of tropical medicine has been attended is in great measure due to the employment of those methods of investigation and teaching so consistently and powerfully employed by that great master of natural science—namely, clearing the mind of tradition and cant, careful observation of facts, hypotheses based on fact, testing such hypotheses by experiment and by their consistency with other facts, and finally, if verified, the fearless application of the proved hypothesis in practice.

Some of you may recollect the opposition encountered by those of us who 10 or 12 years ago were endeavouring to make the study and teaching of tropical medicine a distinct department of medicine. That opposition has, I believe, subsided if not ceased altogether, for it is now generally recognised that this subdivision of medicine is a natural one and one practically necessary, one founded on a well-established principle. That principle, briefly stated, is this—namely, that the possible range of a geographically limited disease depends, not on the influence of climate or locality on the human body or on germs already established in the human body, but as they influence the disease germ itself in and during its passage from one human host to another human host—that is to say, on the disease germ while it is outside the human body. If as regards any given disease germ the climatic and local conditions in any given country are unfavourable to the germ while it is outside the human body, the germ may be imported time after time, but the disease it is responsible for will not spread or become established as an endemic. On the other hand, if the local and climatic conditions are favourable to the germ while outside the human body, once the germ is introduced, given the opportunity, the disease it is responsible for will surely spread.

It so happens that certain germs require for their successful passage from host to host a high atmospheric temperature, or they require animal intermediaries which flourish only in high atmospheric temperatures. These conditions being existent only in tropical or subtropical countries, or in temperate countries during the summer season, the disease produced by the germs referred to can originate and spread in warm countries or seasons only. Malarial disease and its germs are, perhaps, the most familiar example of this principle. Malarial disease is caused by a protozoal organism which in man lives in the red blood corpuscles. Under normal conditions the germ is powerless to leave its human host or to enter another human host. To effect this necessary translation it requires an insect intermediary—a particular kind of mosquito. This mosquito for its well-being, amongst other things, demands a high atmospheric temperature; therefore this insect flourishes in warm climates or in the warm season of temperate climates. Hence human malaria is a disease special to warm climates—that is to say, a tropical disease.

Besides malaria, I could adduce both from human and from veterinary pathology many additional illustrations of this principle. For example, yellow fever, African tick fever, trypanosomiasis, filariasis, certain kinds of spirochætiasis, and so on. In all of these an animal intermediary of tropical habit is necessary *for the transmission* of the germ and therefore of the disease.

There are other tropical diseases for the spread of which no such living intermediary is necessary; nevertheless, high atmospheric temperatures being *required by their germs* in their passage from host to host, these diseases are properly classified as *tropical*. In *their case* the germs require a warm medium in which to accomplish necessary developmental changes which, when complete, qualify the germ to effect successfully a lodgment in the human host. Ankylostomiasis is an example *of this*. If *when it leaves the human* host the egg of the ankylostome does not quickly meet with a warm moist nidus it perishes; if it meets with such a nidus the larva is hatched out and, opportunity serving, enters a new human host, and so the disease it gives rise to is spread.

It is this necessity on the part of the germ for either a tropical intermediary or for a warm medium, such as occur naturally only in tropical countries, that constitutes the main determining factor in the geographical distribution and limitation of tropical disease and which, so to speak, specialises the subject. This is the reason for, and the justification for, specialising the teaching and study of the subject, and this it is that determines the lines on which tropical medicine has to be studied and taught.

What might be described as a corollary pendant to the general principle that the intermediary or medium required by the disease germ is the agent that principally determines the distribution of tropical disease imposes welcome limitations to the field of study. The principal tropical diseases (I do not include in this the skin and the food diseases) are caused either by protozoa or by helminths. *So far as* we accurately know, none of these disease germs are bacterial. The reason for this fact, which pathologists are only beginning to appreciate, lies in the circumstance that the pathogenic bacteria are not materially affected, so far as their viability and *transmission* are concerned, by ordinary atmospheric temperature; neither do they require to undergo developmental changes outside the human body before they can enter another human body, and, therefore, although they may be favoured or the reverse by such, they are not absolutely dependent on any animal or other geographically limited medium. Several bacterial diseases which are often classed as tropical—for example cholera, certain kinds of dysentery, leprosy, plague, Mediterranean fever, &c., are not really tropical. Experience has shown that these diseases can flourish in any climate. It is only because those hygienic and social conditions most favourable to their spread are met with at the *present day in greatest* perfection in the tropics, that they are conventionally regarded as tropical; they have no more real claim to be regarded as tropical than tuberculosis or syphilis has. In times past, and even at the present day, they were or are common enough in some places or conditions in temperate or even in cold countries.

Thus in the study of tropical disease bacteriology may be relegated to quite a secondary place. The student's attention is confined almost entirely to protozoa and helminths, to the special vectors or media of these organisms, to their pathological effects, and to the prophylaxis and treatment of the diseases they give rise to.

I might mention in passing that those who plan schools or courses for the teaching of tropical medicine should recognise this large element of natural history in the subject and that if possible they should include in the teaching staff (1) a protozoologist, (2) a helminthologist, and (3) an arthropodologist (I say arthropodologist because the known intermediaries of the pathogenic protozoa and helminths are nearly all of them either insects, ticks, *or* crustaceans) in addition to the usual pathologist, systematic clinical and hygiene lecturers having at their disposal a suitable hospital with a tropical *clientèle*, besides a laboratory, museum, and

No. 4440.

being dreaded should be welcomed as confirming the cure, if for no other reason.

We meet with two classes of sterile patients suffering from retroflexion of the uterus with secondary changes. 1. It may be set down as a rule with few, if any, exceptions that the nulliparous woman whose uterus is retroflexed at the time of her marriage remains barren. In such cases hysteropexis hypogastria without any other treatment whatever is usually followed by pregnancy. One or two illustrative cases out of many will be given in the sequel. 2. The second class of cases is acquired sterility, often in the form of "one-child sterility." In such cases there is an ascertainable history of pregnancy and puerperal illness following full-term parturition or abnormal interruption of pregnancy. Such a patient is found on examination to have retroflexion of the uterus with complications which often include the results of the slighter forms of pelveo-peritonitis, such as adhesions, closing of the fimbriated ends of the tubes, and sclerosis of portions of the ovaries. Operation in such cases which does not include a full view of the affected parts and ventrifixation in an efficient form is sheer trifling and futility.

There is hardly ever the slightest reaction after this detailed operation in simple cases. It is practically devoid of danger. The pulse and temperature remain almost or altogether normal. No case has given rise to even momentary anxiety, except a case of mysterious acute sepsis which had a fatal termination. This operation has stood the tests of efficiency already mentioned in nearly 300 cases. Many of the operations have been done on account of prolapse of the uterus in comparatively young women, but I do not propose to complicate matters by discussing the treatment of prolapse on the present occasion. I will just remark that for prolapse the operation must be supplemented with colporrhaphy. In only one case was there a partial relapse owing to the imprudence of the patient. The operation had given satisfaction and was repeated, and the result has remained perfectly satisfactory for several years. A considerable proportion of the patients have borne one or more children since the operation. There have been some abortions and one or two cases of slight malpresentation, but not, I believe, to an extent greater than might be expected among the same class of women apart altogether from operation.

I have tried to get at the present state of health of the hospital patients but it is often difficult or impossible to trace them and obtain information. As far as I can learn there has been no case of relapse, even after labour, except the one just referred to.

ILLUSTRATIVE CASES.

CASE 1 (from the . J., aged 28 years, a
patient of Dr. Gardn erperal troubles after
miscarriage. At the 1891, the patient was
suffering from retrol The ovaries not made out
to be involved. *The use of tampon and douche, followed by Schultze's* process, failed to rectify the uterus. Operation of ventrifixation, Oct. 15th, 1891. *Uterus found completely adherent to the floor of* Douglas's space, with broad ligaments folded back, but the ovaries not *dragged down.* The adhesions were easily broken down and the uterus brought into the abdominal wound. Some hæmorrhage from the torn *adhesions.* Ventrifixation completed by eight sutures of catgut, silkworm gut, and fine silk. The wound closed. Easy recovery. This patient consulted me in the early summer of 1892. She was found to be pregnant between four and five months, and, as far as could be made *out*, the uterus was in the normal position, and beyond some sense of dragging about the wound there was nothing to complain of. The patient was advised to go into the Maternity Hospital for her confinement, and it was intended to make careful observations on the process of parturition. Labour came on and was rapidly completed in what was described to me as a perfectly normal fashion. It was only the day after the confinement that I learned what had taken place. The puerperium was carefully observed and there was nothing abnormal about it. Involution of the uterus went on in a perfectly satisfactory way and the patient went home with her child feeling quite well and comfortable, with the exception of some irritation of the bladder. She is again pregnant four months (January, 1894). *She is wearing an* abdominal belt and is quite comfortable, with the exception of one spot near the cicatrix, which is *painful when rubbed.* There is a small nodule at this point and it seems to be produced by an imbedded silkworm-gut suture. The fundus of the uterus is in the normal position for four months pregnancy. The cicatrix is quite firm and apparently adherent to the uterus.

When cases were accumulating with a monotonous regularity of favourable results I sent out a circular letter to medical practitioners who had had one or more patients operated upon by me. For the prompt, careful, and courteous replies sent in answer to my inquiries I desire to express my most grateful thanks.

CASE 2.—Dr. William Moir of Darwen writing in 1897 said: "You performed the operation of ventrifixation on Mrs. T—— of Darwen on May 14th, 1897. She made an excellent recovery. She had been married four or five years and not had a child. Within two months after her return from the Southern Hospital she became pregnant, and I advised her to go to the Maternity to be confined as I thought you would like to see her. She was confined there in 1898. ...... She told me the child had the cord round its neck twice and was dead. The house surgeon told her that was the cause of death. [Although my interest in ventrifixation cases was known to everyone in the hospital I had no opportunity given me of observing the process of parturition.] She had better luck next time. I confined her of a fine male child on Sept. 7th, 1899. The child and mother are both quite well. ......" Dr. Moir goes on to mention the formation of a sinus in the wound which healed again quickly on the removal of a silk ligature.

CASE 3.—Mrs. M. S., aged 2
Hospital in January, 1902. D
the patient engaged for her
letters about the case. In Feb
confinement in March and con
in good position but the vaginal walls were prolapsed. Writing in June, 1904, *Mr. Renshaw said*: "She was confined on May 10th; she had rather a tedious labour, the face under pubes. I used forceps and the child came away without any force. She made a good recovery, got up on June 1st. I examined her on June 5th and found the uterus in good *position, the os just within reach of the index finger.*"

The above is a good illustrative case, indicating the phenomena resulting from relaxation of the pelvic floor. The operation was done before the need for colporrhaphy in prolapse with backward displacement became demonstrated as essential to success.

CASE 4.—Mrs. S., aged 25 years, married two and a half years, one child aged 20 months, one miscarriage. Patient of Dr. W. Stewart, of Bacup. Admitted to Southern Hospital on Nov. 11th, 1902. Previous to abortion in February, 1902, no uterine trouble. Since February menstruation every 14 days, profuse, improvement last two months. Chief symptoms at present time backache and *incontinence of urine* after any considerable exertion. *Examination*: uterus large, in acute *retroflexion*, not fixed, but difficult to raise. As pessaries of various kinds with rest had been *tried all the summer without favourable effect operation* was recommended. Ventrifixation, Nov. 25th, 1902. Routine proceedings. *Usual pessary to support. Nothing worthy of note in post-operation* history except irritability of the bladder as before operation. On Dec. 23rd a *note recording observation on vaginal portion*: "Posterior lips of os diminished in size; anterior lip hypertrophied." *Patient discharged* apparently well on Dec. 30th, 1902. Dr. Stewart, in *letter* dated May 20th, 1908, says: "The patient, Mrs. S——, became pregnant in March, 1904, *delivered* in December. Trouble with bladder the whole time; for last two months incontinence. Duration of labour 12 hours, normal. Pregnant again August, 1907, *delivered* April, 1908. Bladder trouble the first three months, after that no discomfort or bad symptoms. Duration of labour six hours, normal. *Examination yesterday*, involution perfect."

CASE 5.—M. D., aged 31 years, III. para; hospital case. Patient's first pregnancy went to full term five years ago. She was attended by a drunken midwife who neglected to obtain medical assistance during puerperal illness. Five weeks after confinement patient was sent to Withington Poor Law Infirmary suffering from severe abdominal pain and double mammary abscess. She was confined to bed for four months altogether after the confinement. The second pregnancy terminated at full term three and a *half* years after the first—Jan. 19th, 1903. The whole labour did not last more than two hours. Could not suckle the child. *Was able to* get up in 14 days after labour. After the first pregnancy she had complained of pain in the lower part of the abdomen, and *during* the course of the second pregnancy she had again much pain. The pain became very much worse in Nov., 1903, but she did *not seek medical* treatment for six months or so. She was admitted as in-patient of the Southern Hospital in May, 1904. *On examination*, tenderness and resistance in left iliac region but no definite tumour made out by external palpation. P.V. deep *laceration of the cervix with eversion.* Well-marked cicatricial band in left lateral fornix. Uterus in retroflexion, held down by *adhesions*; *tubo-ovarian tumour on both* sides.

Operation: After several weeks of palliative treatment it was resolved *to operate* by abdominal section. Operation, July 12th, 1904. Both ovaries were found imbedded and bound down in adhesions; capsules thickened and ovaries partly sclerosed. The uterus was also firmly bound down with omentum adherent. Both ovaries were resected, about one-third of the left ovary being removed; wounds in ovaries carefully sutured and shreds of adhesion bands cut away. *A fresh* extensive ostium abdominale was made in the right occluded and distended tube, the left tube appeared sufficiently sound to be let alone.

pro 05 (15-21),
any
and was more painful than usual. She came to out-patient room in November complaining of bearing-down. She was admitted for rest and *observation* and remained in the hospital for four weeks. Pregnancy apparently normal except for purely subjective symptoms. She remained under observation as out-patient until the end of April. Nothing unusual noted. Although slight pains began on *June 4th* the patient was not admitted to St. Mary's Hospital until the 6th. The second stage lasted six hours, the third half an-hour. Everything normal. Convalescence quite uneventful. For still another time in hospital cases after ventrifixation *parturition* was so normal that I was not informed until the day after labour. This patient was in much better condition than ever before and was able to suckle her child.

Note.—August 25th, 1906. Seen as out-patient. Involution of uterus complete; position normal; patient in very good health; plenty of milk in breasts.

CASE 6.—Mrs. S. W., *patient of* Dr. J. T. Fraser, Longsight, now aged 43 years, married 21 years. Ten children, seven living, oldest 19 years, youngest two months, at the breast. Has had three children since operation; oldest of these five years. Operation, ventrifixation, Dec. 19th, 1902. Obstetric history: Forceps were used at first three

TABLES OF TROPICAL DISEASES SHOWING OUR PRESENT KNOWLEDGE OF THEIR ETIOLOGY AND MEANS OF PROPAGATION (*Continued*).

TABLE II.—*Diseases Due to Animal Parasites.*

Name of disease.	Causative agent.	Mode of transmission.
Diseases due to Protozoa—		
Malarial fevers. Quartan.	*Plasmodium malariæ* (Laveran, 1881, *sensu stricto*).	Inoculated by mosquitoes of the sub-family *Anophelinæ*.
Malarial fevers. Tertian.	,, *vivax* (Grassi and Feletti, 1890)	
Malarial fevers. Subtertian. Quotidian.	*Laverania malariæ* (Grassi and Feletti, 1890).	
Trypanosomiasis (sleeping sickness).	*Trypanosoma gambiense* (Dutton, 1902).	Inoculated by *Glossina palpalis* and possibly other tsetse flies.
Kala azar	*Leishmania donovani* (Laveran and Mesnil, 1903)	Inoculated by *Cimex rotundatus* (suggested)
Oriental sore.	,, *furunculosa* (Firth, 1891).	Unknown
Relapsing fever. European form.	*Spiroschaudinnia recurrentis* (Lebert, 1874)	Inoculated probably by *Cimex lectularius* and *Pediculus corporis*.
Relapsing fever. African form.	,, *duttoni* (Novy and Knapp, 1906)	Inoculated by *Ornithodoros moubata*.
Yaws.	*Treponema pertenue* (Castellani, 1905).	Conveyed by flies on abraded surfaces—contact.
Dysentery. Balantidium dysentery.	*Balantidium coli* (Malmsten, 1857)	Fouled water or food, contaminated by sewage, flies, &c.
Dysentery. Amœbic ,, Tropical liver abscess	*Entamœba histolytica* (Schaudinn, 1903).	
Diseases due to Metazoan Parasites—		
Trematode infection (Distomatosis). Pulmonary (endemic hæmoptysis).	*Paragonimus westermanii* (Kerbert, 1878).	Probably food or water containing cercaria or other larval form
Hepatic.	*Clonorchis sinensis* (Cobbold, 1875).	
	Opisthorchis noverca Braun, 1903.	
	Fasciola hepatica Linnæus, 1758.	
Intestinal.	*Fasciolopsis buski* (Lankester, 1857).	
	,, *rathouisi* (Poirier, 1887)	
	Heterophyes heterophyes (Bilharz, 1852)	
	Gastrodiscus hominis (Lewis and McConnell, 1876)	
	Cladorchis watsoni (Conyngham, 1904)	
Vesical. (Endemic hæmaturia.)	*Schistosoma hæmatobium* (Bilharz, 1852)	Possibly by swallowing cercaria or other larval form. Infection through the skin, the urethra, or the anus suggested
	Schistosoma mansoni Sambon, 1907	
	,, *japonicum* Katsurada, 1904	
Cestode infection (Tæniasis). Intestinal.	*Tænia saginata* Goeze, 1782.	By eating beef infected with larval form (*Cysticercus bovis*).
	,, *africana* Linstow, 1900	Possibly by eating the flesh of the zebra.
	,, *hominis* Linstow, 1902.	Food containing cysticercus.
	,, *solium* (Linnæus, 1758)	By eating under-cooked or under-cured pork
	Hymenolepis nana (Siebold, 1852)	Food soiled by the excrements of rats and mice
	,, *diminuta* (Rudolphi, 1819)	Food containing infected larva or imago of *Asopia farinalis*
	Davainea madagascariensis (Davaine, 1869)	Food or water contaminated by cockroaches probable carriers of cystic stage.
	,, *asiatica* (Linstow, 1901)	Unknown.
	Dipylidium caninum (Linnæus, 1758)	May be conveyed by dogs in licking after biting infected fleas or lice.
	Dibothriocephalus latus (Linnæus, 1758)	Infection probably takes place through eating fish
	Diplogonoporus grandis (Blanchard, 1894)	
Somatic. (Hydatid disease.)	*Echinococcus granulosus* (Batsch, 1786, Zeder, 1803)	Contaminated food or water. Hands soiled in petting dogs.
	Sparganum mansoni (Cobbold, 1882)	Probably by means of water
	,, *baxteri* Sambon, 1907	
	,, *proliferum* (Ijima, 1905)	
Roundworm infection. Ankylostomiasis.	*Ankylostoma duodenale* Dubini, 1843	Either passively by means of contaminated food or by soiled hands, or actively through the skin.
	Necator americanus (Stiles, 1902)	
	Triodontophorus deminutus Railliet and Henry, 1905.	Unknown.
Strongyloidosis (Cochin China diarrhœa).	*Strongyloides stercoralis* (Bavay, 1877)	Either passively by means of contaminated food or actively through the skin
Ascaris.	*Ascaris lumbricoides* Linnæus, 1758.	Contaminated water, vegetables, and fruit. [illegible]
Oxyuriasis.	*Oxyuris vermicularis* (Linnæus, 1758)	Contaminated food. Soiled hands. Flies [illegible] eggs.
Trichocephaliasis.	*Trichocephalus trichiurus* (Linnæus, 1771)	Contaminated food or water.
	Œsophagostomum brumpti Railliet and Henry, 1905.	Probably by means of contaminated water.
	Physaloptera mordens Leiper, 1907	Unknown.
	Gnathostoma siamense (Levinsen, 1889)	

of the cæcum and appendix was the subject of one of the Arris and Gale lectures delivered at the Royal College of Surgeons of England in 1907. This lecture was founded upon the results of injection. I venture to think that the study of post-mortem pathology is equally useful and have confined my attention to that.

The Lymphatics Involved in Growths in the Cæcal Region.

This includes the growths which have also invaded the ascending colon or which are entirely in the latter portion of bowel at its commencement. There were 17 cases in all, of which 16 could be examined, 14 post mortem and two by the inspection of the specimens removed at operation. The situation of the glands was more or less constant. In only three-quarters of the cases were the enlarged glands infected. The glands were situated as follows. 1. In the ileo-colic angle there were always some found. The exact situation of these with relation to the bowel varied. Mostly they were more or less in close contact with the bowel, but at times they were at a little distance. 2. Continuous with (1) was a chain along the inner side of, and in close contact with, the ascending colon. The number of these and the height to which they ascended on the colon varied. In general they were only found on that part of the colon immediately above the ileo-cæcal valve. In a quarter of the cases these glands were not observed. In one case after excision of the growth I found some of this chain of glands left from a too low division of the colon. 3. Continuous with (1) were a few small glands on the upper border of the ileum. These varied in numbers. Generally only one or two were found. In one case a chain extended for five inches along the small intestine. 4. In two cases there were two or three glands found more posteriorly—that is behind the growth. In three the ileo-colic glands extended nearly to the bifurcation of the ileo-colic artery. In a further case of a very extensive growth, which had spread widely in the retroperitoneal tissues and the peritoneum, glands were found around the head of the pancreas. How the spread had taken place it was impossible to say, since the growth was very extensive and other glands, if any had been involved, had been swallowed up in the primary growth. In only this latter case could glandular involvement be said to be a factor prohibiting the radical operation. It was not, however, the only factor.

The operation for a growth in the cæcal region should be one which aims at the removal of the cæcum, ascending colon nearly to the hepatic flexure (this is necessary since the right colic artery must be sacrificed not because I have found any glands along the trunk of the vessel, but it often comes off in common with the ileo-colic, or, if not, at its commencement it lies very near to the latter, and if a free excision of the tissue around the ileo-colic is done the right colic cannot be spared), the retroperitoneal tissues and the leaf of peritoneum covering the two named vessels, the lower six inches or so of the ileum, and the termination of the mesentery corresponding to the ileal branch of the ileo-colic artery. This can be attained in the following manner. The abdominal wall is incised in the right semilunar line. The peritoneum is divided on the outer side of the cæcum and ascending colon. With two fingers in the hole so made used as a director the peritoneum can be divided up as high as the kidney. Caution must be exercised then because of the duodenum. When the latter is identified the peritoneum may be further divided and the colon separated from the kidney and duodenum. The cæcum, ascending colon, and some retroperitoneal tissue are then stripped up from the posterior abdominal wall towards the mid-line. The ureter and spermatic vessels are exposed and preserved. The lower ileum, cæcum, ascending colon, some retroperitoneal tissue, and a leaf of peritoneum can then be drawn out of the abdominal cavity. Removal is best commenced from above. The colon is cut somewhere about the level of the hepatic flexure. In a moderately spare subject the vessels can be recognised behind the leaf of peritoneum. These are the right colic and the ileo-colic arteries. They as often as not come from a common trunk. If they can be recognised so much the better. If not, by dividing along the line of uplifted peritoneum from above down, the first large vessel will be the right colic artery. The ileo-colic artery is then ligatured. The common trunk of these two vessels may only be encountered. This depends upon how far it has been possible to raise the peritoneum from the posterior abdominal wall and also upon the anatomical arrangement of the vessels. When the common trunk or the separate branches have been divided the section is carried down to the lower ileum so as to remove about the last six inches or so of it. Particular attention must be paid to the last intestinal branch of the superior mesenteric artery, and it should not be injured unless a corresponding length of small gut be removed. It is advisable to see this branch if possible and to plan the cut in the mesentery so that the ileum will be sectioned at the junction of the anastomosis of the ileo-colic and superior mesenteric arteries. In one case after removal of a cæcal growth there was gangrene of some length of small bowel. It will be easier to avoid cutting the intestinal branches of the superior mesenteric artery, I believe, if the section be commenced from above and the mesentery and lower ileum be left to the last. For by working in this way as more and more of the colon is freed it can be carried outside of the line of the direct field of operation, and by drawing upon it the lower mesentery can be stretched and a good view obtained of the anastomosis probably. There may be some glands behind the cæcum, but they are closely in contact with the latter and will readily strip off the iliac fossa. The end of the divided colon is closed and the ileum joined to the most accessible part of the transverse colon.

The Lymphatic Drain of the Bowel supplied by the Middle Colic Artery.

I confess my numbers here are far too small to be of any positive value and I only mention my results as being suggestive.

The hepatic flexure.—Five cases only in this series were at the hepatic flexure. Two of these were examined post mortem; in both glands were present near to the growth and also in the mesocolon at a variable distance from the transverse colon and extending some little way from the primary growth. One further case was successfully excised but is too recent to be of any value. Glands were present in the vicinity of the growth. In two cases the growth was adherent posteriorly and anastomosis was the only possibility. Growths in the hepatic flexure would seem to be peculiarly bad from the surgical standpoint. The arrangement of the peritoneum here varies; as often as not there is no mesentery to the colon which is in intimate contact with the duodenum and pancreas. No wonder is it that adhesions are early in these growths and that excision, as I judge from literature, has not been very often possible. The hepatic flexure is a more or less fixed part of the colon, but it can be readily made mobile. This is secured by a free division of the peritoneum on the outer side of the ascending colon and the serous membrane as it passes from the colon to the liver. If the gastro-colic omentum be also divided a considerable range of mobility is given to this part of the colon. This I should suggest as the plan of procedure in the removal of these growths. I suggest also that the corresponding half (or as much as can be) of the mesocolon requires removal in order to secure the lymphatics which pass here. The section of the bowel may be begun at the transverse colon and will be somewhere about the middle of the latter as the right branch of the artery will be cut. If the ascending colon has been freed by division of the peritoneum along the outer aspect it probably may be joined to the cut end of the transverse colon. In separating a growth from the pancreas and duodenum only a little of surrounding tissues can be removed. The amount will depend upon the extent and development of the mesentery in the region. By commencing the section at the transverse colon a clearer view of the parts will be given.

The transverse colon.—There were only three growths here. One was successfully excised. This was a large growth in the centre of the transverse colon. The glands in the immediate vicinity only were affected. Cancer cells were not found in the glands. Nearly three years later the patient developed intestinal obstruction and died. The obstruction was caused by adhesions. There was no evidence of any recurrence of the cancer. In a second case the growth was irremoveable. There were many enlarged glands in the mesocolon and in the great omentum. Lateral anastomosis was performed. One case was examined post mortem and here glands only close to the growth were enlarged.

germ from arm to arm. The mosquito not only conveys the malaria germ but *it also serves as* a medium in which that germ undergoes certain developmental changes necessary for its existence as a species, as well as for its successful introduction into a fresh human host. These changes are of a sexual nature and include impregnation of the female malaria germ by the male malaria germ, and result in the development of a multitude of young malaria germs which, should they chance on the opportunity of being introduced into human blood by their mosquito nurse and vector when she again bites a human victim, *live and multiply, generation following* generation for any time up to two or three years. Until the developmental changes occurring in the mosquito, changes which take some ten days to effect, are completed the mosquito may bite but she will not infect. The same principle holds good in the case of those other animal-intermediary-using protozoal germs whose life-histories have been worked out, and we are justified by analogy in conjecturing that they also apply to many similar protozoal germs whose life-histories have as yet not been fully ascertained.

. In a word, certain blood-haunting protozoa requiring an insect or other arthropod vector make use of that vector as a medium for sexual development. May we regard this as a general law applicable to *all* such blood-haunting protozoa ?

Unfortunately, there are certain of these pathogenic protozoa in respect to which, notwithstanding their employment of an insect or other arthropod vector, careful research by highly trained and competent investigators has failed to demonstrate convincingly sexual changes within their *respective vectors. The trypanosomes*, now known to be a large and important class of pathogenic protozoa, are notorious examples of this. An indubitable sexual stage of the germ of sleeping sickness, *Trypanosoma gambiense*, the most important of these, has not hitherto been clearly demonstrated in its vector, the tsetse fly, *Glossina palpalis.*

I shall endeavour to examine the case as regards this sleeping sickness trypanosome, for, depend upon it, if the law I have formulated applies to this trypanosome, or any trypanosome for that matter, it applies to all trypanosomes; if it does not apply to this trypanosome it does not apply to any trypanosome. If there be such a law it is of the utmost practical importance that we should not merely suspect its existence but that we should be sure of it. The subject is of more than theoretical interest. Accurate knowledge is the *true* and proper basis of practical medicine, especially of preventive medicine. Witness what it has done for the prevention of malaria and yellow fever. Half knowledge means half-hearted measures; full knowledge means hopefulness in endeavour, precision in directing, and economy in carrying out.

I propose to deal with the arguments both for and against this what I might designate hypothetical law, taking, as I have said, the sleeping sickness trypanosome as a text. I shall allude, though very briefly, to the arguments in favour of the law, more fully to those against it.

As regards the former, a principal argument is based on analogy. I am fully aware that this method of reasoning must not be carried too far. It has a certain value, however; in the present instance it is distinctly favourable.

There *can no longer* be any doubt that the trypanosome of sleeping sickness is conveyed principally, although *perhaps* not exclusively, by the tsetse fly, *Glossina palpalis*. Direct experiment—the correspondence of the topical as well as of the regional distribution of the fly and of the disease—practically proves this. If the fly acts merely as a mechanical vector of the trypanosome, why is the trypanosome not conveyed more frequently than is the case by other biting insects, such as mosquitoes, fleas, bugs, tabanidæ, &c., and therefore to be found along with its disease, sleeping sickness, not merely, as is the case, on the banks of African rivers and on the shores of African lakes, but everywhere where man-biting insects occur? You can vaccinate with a lancet, a needle, or even with a thorn; in fact, with anything that will scratch. Surely this predilection of the trypanosome for *Glossina palpalis* must be that *Glossina palpalis* is not merely mechanically serviceable to the trypanosome but physiologically necessary. What more probable than that this physiological necessity is identical with that of those other protozoal organisms under similar circumstances whose life-histories have been ascertained—namely, sexual development.

Most zoologists hold that all animals, protozoa as well as metazoa, require *from time to time to undergo sexual changes.* It is true that with many of the protozoa reproduction is effected principally by a process of division or by a process of budding carried through during many generations, hundreds or thousands it may be. But there comes a time, even in these, when the asexual reproductive energy is spent, as it were, and when the organism concerned to avert its extinction as a species has *to assume sexual characters and* reproduce sexually, a process which in some mysterious way resuscitates its asexual reproductive faculty, thereby enabling it once more to revert to simple division or budding for another hundred or thousand or more generations. It is so as regards the malaria parasite and its congeners, and it has been proved to be so as regards the humbler fresh water amœba. Surely the same must apply *to organisms so highly* developed as the trypanosomes. In those blood-haunting protozoa whose life-history we know—again I must adduce the malaria parasites—this sexual process is carried out in the insect vector, the mosquito, so may it be with the trypanosome in its insect vector, the tsetse fly. Indeed, special forms of the trypanosome occur in the blood of the vertebrate host which, in the opinion of some observers, are early sexual forms possessing sexual characters which are found to become more accentuated as they are followed into the alimentary canal of the tsetse fly. These forms, which though alive, are, as has *been proved experimentally, incapable* of multiplying in the vertebrate as the asexual forms so readily do. The reason for this failure of a particular phase of an organism otherwise so infective to infect is conjectured to be that the function of the phase concerned being sexual it lies outside the human body and can be carried out only in its appropriate medium—that is to say, the tsetse fly.

Such are the leading arguments in favour of a sexual phase within its insect vector in the case of *Trypanosoma gambiense. Similar arguments apply to similar* protozoa. These arguments distinctly support the law I plead for.

The leading arguments against such a law, against the occurrence of a sexual phase in the insect vectors of trypanosomes and similar protozoa, are: (1) a sexual phase has not been conclusively demonstrated in any trypanosome; (2) if there be a sexual phase it may be passed in the vertebrate and not in the insect host; (3) the trypanosomes can be inoculated artificially, sexual changes may therefore be unnecessary for their propagation; and (4) an insect intermediary is apparently unnecessary in at least one species of trypanosome and therefore is not a biological necessity in *Trypanosoma gambiense* or in any species of trypanosome.

1. A sexual phase has not been conclusively demonstrated in any trypanosome. This is one of those negative arguments to which experience in other departments of natural history has shown that too much weight must not be assigned. We must bear in mind the difficulty in working with an organism so minute as a trypanosome and also with one so refractory to experimentation and dissection as a tsetse fly. Several forms under such conditions might readily escape detection. The more or less positive argument of analogy may very well be set against this negative argument of non-detection.

2. If the trypanosome does possess a sexual phase this may be passed, as in the case of certain nematodes—notably the *blood worms*—in the vertebrate and not in the invertebrate host. Indeed, Breinl and Kinghorn have shown that in *Trypanosoma lewisi* and in *Trypanosoma gambiense* there occur at more or less definite intervals certain cytological phenomena which these observers suggest may be of a sexual nature. If this suggestion represents the truth then the respective insect intermediaries of these parasites may function merely as mechanical carriers. The observations referred to, though of great interest, have not as yet been carried to that point which *warrants the conclusion that the* cytological changes in question are really of a sexual nature. Even supposing they are of this nature, it does not follow that the sexual process is concluded in the vertebrate or that they are not preliminary to further and final changes in the insect, as in the case of the plasmodidæ.

3. It has been argued that as the trypanosomes can be successfully inoculated through a long series of vertebrate hosts their propagation does not necessitate at any time a sexual stage in the invertebrate intermediary. I *do not* attach much importance to this argument. We know of other protozoal germs which can be similarly transmitted

on until the inferior mesenteric artery itself be seen. By spreading out the loop of bowel the individual branches of the artery may be seen unless there be an excess of fat. The intestine is then divided above and the incision in the mesentery is carried in to the trunk of the sigmoid artery, which is ligatured. The section may then be carried down the mesentery so planned as to avoid the superior hæmorrhoidal artery which will be found in close proximity to the pelvic brim, but with the intestine and mesentery on the stretch of course it may be a little displaced. The lower end of the colon is divided somewhere about the level of the pelvic brim. This will insure the intactness of the superior hæmorrhoidal artery and in addition will leave sufficient stump to enable an intra-abdominal anastomosis to be performed. If the separate vessels are not identified because of excessive fat then the operation may be conducted in precisely the same manner. The bowel may be divided at the upper end almost as high as the iliac crest without danger of the left colic artery. If the mesentery be divided now directly inwards towards the base of the sacrum the first large trunk will be the sigmoid artery. This vessel can thus be identified and the rest of the operation is as before. If the growth be situated low down in the pelvic colon, that is in that part supplied by the superior hæmorrhoidal artery, then the latter must be sacrificed and also the retro-peritoneal tissues in front of the sacrum. This operation cannot probably be completed intra-abdominally. It has always seemed to me a colostomy could not be avoided. But if this portion of bowel can be spared the upper end of the divided colon, which has been rendered mobile by the division of the peritoneum on its outer border, can be brought straight down to it.

Since preparing the above I have read a very interesting paper by Mr. B. G. A. Moynihan. This is in direct contradiction to my observations. Mr. Moynihan says that there is always a gland on the inferior mesenteric artery which must be removed. This gland would presumably lie about an inch or so higher than the line of section which I have indicated. Personally, I have not been able to find glands here except in the few instances mentioned already. It is what I should have expected to be the natural finding. But finding it so rarely, and believing that it was not the glands which formed the great contra-indication to the radical operation, and also thinking that ligature of the inferior mesenteric artery would entail a very extensive resection of the descending colon, I have advised the more restricted removal than that advocated by Mr. Moynihan. In the cases in which I have seen glands on the inferior mesenteric artery there has been more than one, and I have considered in such cases that all attempts at a radical operation would be out of the question. Mr. Moynihan considers that this gland which he describes and has found constant is the highest of the chain and must always be removed. I have always considered that ligature of the inferior mesenteric artery would necessitate excision of the greater part of the descending colon and that union of the two ends would be impracticable. But Mr. Moynihan has shown that this is not so. He says that the upper end of the sigmoid flexure is freely supplied with blood even after the inferior mesenteric trunk has been divided. Mr. Moynihan describes the operation he practises for cancer in this region, and I cannot do otherwise than cordially recommend anyone interested in the subject to read the paper where everything is most clearly stated. The paper is in *Surgery, Gynæcology, and Obstetrics* for May, 1908.

Clinical Features.

It is best to differentiate the growths in the cæcal region in considering the clinical characters, for they are not in all respects similar to those elsewhere.

The main clinical characters of growths in the cæcal region.—There were 11 males and six females. The youngest patient was 30 and the oldest 73 years. The ages ranged in decades were as follows:—

Between 30 and 40 years...	2 cases
„ 40 „ 50 „	6 „
„ 50 „ 60 „	4 „
„ 60 „ 70 „	4 „
Over 70 years...	1 case.

In two cases there were apparently two separate abdominal growths. In one a small growth in the stomach and in the second an extensive one in the rectum were present in addition to that in the cæcal region. In the latter the abdominal symptoms were due to the rectal growth and it must remain unknown whether there were any which could be attributed to the cæcal one.

The most constant symptom is pain. This was in nine out of 15 cases of the nature of colic. In others it was a more or less persistent pain in the right iliac fossa without reference to any intestinal disturbance. Apart from the colicky pains in the majority there was no other evidence of chronic intestinal obstruction. The bowels were not constipated neither were any coils in peristalsis seen, and it may be mentioned that post-mortem examination often did not show any hypertrophy of the small gut, as would be anticipated if obstruction had been present. Two, however, did suffer definitely from obstruction which ended subacutely, and a further case gave a history of having been obstructed for three days a short time before he came under observation. In the latter three the bowels were definitely constipated, but in the others there was little alteration from what may be considered normal to each of the individual patients. One patient passed a large quantity of tarry material at the beginning of his illness (six months before coming under observation). This was presumably blood. In no other instance was any blood noticed by the patient. On two occasions there was at times diarrhœa, the motions containing a little mucus. Loss of flesh was constant in all and it was often a very noticeable feature of the illness.

The presence of a swelling was very constant in cæcal carcinoma. The growths here are often of the large, bossy, and luxuriantly growing type and form masses of large dimensions. But in addition also the cæcum is quite superficial and easily palpable. In two a large abscess was present and a tumour could not be felt. In one (the case which exhibited a rectal growth) the tumour was very small and not palpable. In one (an obese patient) a tumour was only felt under anæsthesia. In two cases chronic obstruction had ended subacutely and abdominal distension was marked when the patients first came under observation. In neither of these was a tumour palpable, but in all probability in a flat abdomen it would have been readily felt.

It must not be inferred that symptoms have been in existence for some time before a tumour may be detected clinically. In two the swelling was present practically from the time when the symptoms commenced. In two others it was known to be present very shortly after pain in the region was first experienced. In the remaining cases, judging from the size and easy palpation of the tumour, it could have in all probability been detected at a much earlier period.

The main symptoms of a cæcal growth may be said to be pain, colicky or a persistent ache, generally absence of true obstruction, normal regularity of the bowels, and the presence of a tumour, associated with a progressive loss of flesh and deterioration of health. It may be noted that it is not uncommon to have a little fever. The thermometer may register 99° F, or a little higher at times even in the absence of suppuration. This may be septic absorption or perhaps in some way due to the growth. This has occasionally been noted in uncomplicated growths elsewhere in the colon.

Three cases had the complication of suppuration around the growth. In one of these the onset was as a subacute appendicitis, but after draining the abscess for some weeks a firm swelling became palpable and later it fungated through the sinus. There were no symptoms of obstruction. In the second case there was a large abscess which had probably been present for some weeks. In the third case there was a very small collection of pus around the growth, not sufficient to cause adhesions which prevented removal. The similarity in such cases to appendicitis is marked, as it may be in uncomplicated cases of cæcal cancer.

Continued irritation as a possible etiological factor could not be asserted to be present in a single case. It may be thought that chronic constipation and an overloaded cæcum, stercoral ulceration, or a chronic appendicitis might have some influence, as irritation seems to play a part in some cases of cancer elsewhere. Chronic appendicitis seems not infrequently to have been present in many cases of carcinoma of the appendix. In not a single instance was it present in this series. Chronic constipation was nearly always absent. In only two cases have I noted it. Judging from the frequency which many writers of great experience regard cancer of the stomach to be preceded by a simple ulcer it might be thought that a similar condition would prevail in the rest doctrines of evolution. I have endeavoured to explain how a certain intimacy of association between intermediary and definitive host is essential for the parasites employing them, and how this association must not be confined exclusively, as regards either host or intermediary, to a single individual of each or either.

The protozoa and possibly the nematodes acknowledge, in my opinion, a very remote ancestry—that is to say, they became parasitic very early in the growth of the phylogenetic tree. There are other parasites, however, which manifestly must have adopted the parasitic habit very much later in the history of the animal kingdom. Certain insects, which probably from the beginning were closely associated with vertebrates and lived on the juices of these vertebrates, finding that they no longer required their wings, gradually dropped these wings and permanently attached themselves to their vertebrate food source. Such are many of the hemipterous and apterous insects, lice, &c. Similarly the ancestors of the acari, of some of the ticks, and other ectozoa have gradually fallen into complete or partial parasitic habits; certain bugs and ticks are even at the present day in process of acquiring this habit. I have no doubt that, as with the modern mosquitoes, ticks, and bugs, the ancestors of the existing huge ectozoal fauna of man and other vertebrates fostered parasites which they possessed in common with their respective vertebrate associates. What, you may ask, has become of these parasites? Have they failed to do what other parasites and the hosts of other parasites have succeeded in doing; have they failed to adapt themselves to their gradually changing environment? And if they have succeeded in adapting themselves how did they manage to overcome certain obvious difficulties, for example, that which I have indicated as being so necessary to such parasites, the go-between habit of at least one of the hosts, that necessity which is so efficiently subserved in the case of the malaria parasite by the mosquito?

I believe that this has been effected by a process of reversion, the asexual form of the parasite gradually re-acquiring, for purposes of propagation, the capacity and habit of direct passage from vertebrate to vertebrate, the necessity for sexual reinvigoration from time to time being still subserved by the ectozoal descendant of an originally free insect or other arthropod.

That is how I would explain the apparent absence of an insect intermediary in the trypanosome disease, dourine. Some apterous, hemipterous, or semi-parasitic insect phylogenetically allied to the tsetse flies is its intermediary. This insect has not been found, probably because it has not been looked for in the proper way.

I hold, therefore, that the existence of a sexual phase in the sleeping sickness trypanosome, *Trypanosoma gambiense*, and other trypanosomes is more than probable, that it has not been disproved, and that the argument founded on the natural direct communicability of dourine in the apparent absence of an insect intermediary for its germ, *Trypanosoma equiperdum*, is not valid, and that the evidence hitherto adduced is distinctly in favour of a law to the effect that blood-haunting protozoa having arthropod vectors require, and make use of, these vectors for necessary sexual development. Why the sexual stage of these parasites is passed in the arthropod and not in the vertebrate I cannot explain, any more than I can explain the contrary arrangement which obtains in the blood-haunting nematodes, the sexual stage in their case being passed in the vertebrate host, the asexual in the insect.

I have no doubt, while listening to these remarks, it has occurred to some of you, as it has often occurred to me, that the principles I have endeavoured to express have a wider application than that which I have directly indicated, that our disease germs and our ectozoa—insignificant though the latter appear to be—are correlated more frequently than is generally suspected, that, in fact, there is a necessary relationship between them. Indeed, in some instances we are beginning to find this to be the case. I have no doubt some of you dimly perceive that the whole of this subject, which recent studies in tropical medicine have done so much to develop, may have important practical bearings, that it is not an exclusively tropical one, and that in the near future it may find an application in the explanation of the pathogenesis and, therefore, an application in the prevention of many diseases of temperate as well as of tropical climates. It is a tempting theme to enlarge on. I must forbear. I feel I have already been sufficiently hypothetical. Perhaps some future Huxley lecturer will atone for my sins in this respect and supply the facts which, I acknowledge, are still lacking fully to establish the several hypotheses I have endeavoured to express.

THE TREATMENT OF INOPERABLE CANCER.[1]

BY HENRY MORRIS, M.A., M.B. LOND.,
PRESIDENT OF THE ROYAL COLLEGE OF SURGEONS OF ENGLAND; CONSULTING SURGEON TO, AND EMERITUS LECTURER ON SURGERY AT, THE MIDDLESEX HOSPITAL, LONDON.

WHEN the Central Committee of the International Society of Surgery honoured me in March, 1906, by asking me to read a paper at the Congress in 1908 on the treatment of inoperable cancer they were, I believe, aware that I had opened a discussion on the same subject at the meeting of the British Medical Association at Manchester in August, 1902. It is now, as I write, about five and a half years since that discussion took place, and with but little exception the question stands to-day much as it did then. Increased experience and the mere lapse of time have enabled some of the methods then under consideration to be more justly appraised, and certain others which have since then been claimed to be cancer cures have been brought forward, but there has been, unfortunately, no definite advance towards the discovery of a reliable cure. If, therefore, I borrow somewhat freely from my former paper, it is on the old Greek principle that having once said what one wished to say, one can hardly say it twice, *δὶς δὲ οὐκ ἐνδέχεται*, except by repeating one's own words.

I will begin by quoting verbatim the definition I gave in 1902 of the meaning of the terms the "treatment of inoperable cancer."

"The term 'cancer' is used in a general sense to include all forms of malignant new growths, and therefore embraces rodent ulcer, sarcoma, and lympho-sarcoma, and endothelioma as well as epithelioma and other varieties of carcinoma. The term 'inoperable' means that the disease cannot be entirely eradicated, or permanent immunity hoped for, by a cutting operation, or by the actual cautery, or any escharotic aiding the knife. It does not imply that malignant disease is of constitutional as distinct from local origin and that as such it is ineradicable. On the contrary, I take it for granted that cancer is at first, and so far as rodent cancer is concerned throughout, a local disease. But even on this view there are four groups of inoperable cases. They are: (1) primary cancer affecting inaccessible parts and organs; (2) primary cancer which though originating in an accessible part or organ of the body has been allowed to extend beyond the limits within which an operation is prudent and complete removal possible; (3) certain cases of acute diffuse carcinoma and very rapidly growing or widely infiltrating new growths of exceptionally virulent character; and (4) recurrent cancer, where the disease has recurred in multiple metastatic foci or in parts beyond the limits of removal. Many of the cases included in these groups are submitted to operation for the purpose of palliating symptoms or prolonging life. Hence the term 'treatment' as applied to inoperable cancer means one of two things: (1) the employment of remedies and methods other than the knife, to cure, ameliorate, or retard the disease, as well as to prevent relapses after its removal; or (2) the employment of the knife to give relief from pain, to prolong life, to restore function, and otherwise to make the patient's condition more tolerable."

PALLIATIVE OPERATIONS.

In a paper which is intended merely to introduce a discussion it is of course quite impossible to consider all the many palliative operations which are resorted to in cancer of the various organs and regions of the body. Only the principal methods employed to combat cancer in the organs and parts most commonly affected will be referred to and these only with regard to their reputed or accredited beneficial results.

[1] A paper read at the International Surgical Congress at Brussels on Sept. 24th, 1908.

on until the inferior mesenteric artery itself be seen. By spreading out the loop of bowel the individual branches of the artery may be seen unless there be an excess of fat. The intestine is then divided above and the incision in the mesentery is carried in to the trunk of the sigmoid artery, which is ligatured. The section may then be carried down, the mesentery so planned as to avoid the superior hæmorrhoidal artery which will be found in close proximity to the pelvic brim, but with the intestine and mesentery on the stretch of course it may be a little displaced. The lower end of the colon is divided somewhere about the level of the pelvic brim. This will insure the intactness of the superior hæmorrhoidal artery and in addition will leave sufficient stump to enable an intra-abdominal anastomosis to be performed. If the separate vessels are not identified because of excessive fat then the operation may be conducted in precisely the same manner. The bowel may be divided at the upper end almost as high as the iliac crest without danger of the left colic artery. If the mesentery be divided now directly inwards towards the base of the sacrum the first large trunk will be the sigmoid artery. This vessel can thus be identified and the rest of the operation is as before. If the growth be situated low down in the pelvic colon, that is in that part supplied by the superior hæmorrhoidal artery, then the latter must be sacrificed and also the retroperitoneal tissues in front of the sacrum. This operation cannot probably be completed intra-abdominally. It has always seemed to me a colostomy could not be avoided. But if this portion of bowel can be spared the upper end of the divided colon, which has been rendered mobile by the division of the peritoneum on its outer border, can be brought straight down to it.

Since preparing the above I have read a very interesting paper by Mr. B. G. A. Moynihan. This is in direct contradiction to my observations. Mr. Moynihan says that there is always a gland on the inferior mesenteric artery which must be removed. This gland would presumably lie about an inch or so higher than the line of section which I have indicated. Personally, I have not been able to find glands here except in the few instances mentioned already. It is what I should have expected to be the natural finding. But finding it so rarely, and believing that it was not the glands which formed the great contra-indication to the radical operation, and also thinking that ligature of the inferior mesenteric artery would entail a very extensive resection of the descending colon, I have advised the more restricted removal than that advocated by Mr. Moynihan. In the cases in which I have seen glands on the inferior mesenteric artery there has been more than one, and I have considered in such cases that all attempts at a radical operation would be out of the question. Mr. Moynihan considers that this gland which he describes and has found constant is the highest of the chain and must always be removed. I have always considered that ligature of the inferior mesenteric artery would necessitate excision of the greater part of the descending colon and that union of the two ends would be impracticable. But Mr. Moynihan has shown that this is not so. He says that the upper end of the sigmoid flexure is freely supplied with blood even after the inferior mesenteric trunk has been divided. Mr. Moynihan describes the operation he practises for cancer in this region, and I cannot do otherwise than cordially recommend anyone interested in the subject to read the paper where everything is most clearly stated. The paper is in *Surgery, Gynæcology, and Obstetrics* for May, 1908.

Clinical Features.

It is best to differentiate the growths in the cæcal region in considering the clinical characters, for they are not in all respects similar to those elsewhere.

The main clinical characters of growths in the cæcal region.—There were 11 males and six females. The youngest patient was 30 and the oldest 73 years. The ages ranged in decades were as follows:—

Between 30 and 40 years...	2 cases
„ 40 „ 50 „	6 „
„ 50 „ 60 „	4 „
„ 60 „ 70 „	4 „
Over 70 years...	1 case.

In two cases there were apparently two separate abdominal growths. In one a small growth in the stomach and in the second an extensive one in the rectum were present in addition to that in the cæcal region. In the latter the abdominal symptoms were due to the rectal growth and it must remain unknown whether there were any which could be attributed to the cæcal one.

The most constant symptom is pain. This was in nine out of 15 cases of the nature of colic. In others it was a more or less persistent pain in the right iliac fossa without reference to any intestinal disturbance. Apart from the colicky pains in the majority there was no other evidence of chronic intestinal obstruction. The bowels were not constipated neither were any coils in peristalsis seen, and it may be mentioned that post-mortem examination often did not show any hypertrophy of the small gut, as would be anticipated if obstruction had been present. Two, however, did suffer definitely from obstruction which ended subacutely, and a further case gave a history of having been obstructed for three days a short time before he came under observation. In the latter three the bowels were definitely constipated, but in the others there was little alteration from what may be considered normal to each of the individual patients. One patient passed a large quantity of tarry material at the beginning of his illness (six months before coming under observation). This was presumably blood. In no other instance was any blood noticed by the patient. On two occasions there was at times diarrhœa, the motions containing a little mucus. Loss of flesh was constant in all and it was often a very noticeable feature of the illness.

The presence of a swelling was very constant in cæcal carcinoma. The growths here are often of the large, bossy, and luxuriantly growing type and form masses of large dimensions. But in addition also the cæcum is quite superficial and easily palpable. In two a large abscess was present and a tumour could not be felt. In one (the case which exhibited a rectal growth) the tumour was very small and not palpable. In one (an obese patient) a tumour was only felt under anæsthesia. In two cases chronic obstruction had ended subacutely and abdominal distension was marked when the patients first came under observation. In neither of these was a tumour palpable, but in all probability in a flat abdomen it would have been readily felt.

It must not be inferred that symptoms have been in existence for some time before a tumour may be detected clinically. In two the swelling was present practically from the time when the symptoms commenced. In two others it was known to be present very shortly after pain in the region was first experienced. In the remaining cases, judging from the size and easy palpation of the tumour, it could have in all probability been detected at a much earlier period.

The main symptoms of a cæcal growth may be said to be pain, colicky or a persistent ache, generally absence of true obstruction, normal regularity of the bowels, and the presence of a tumour, associated with a progressive loss of flesh and deterioration of health. It may be noted that it is not uncommon to have a little fever. The thermometer may register 99° F. or a little higher at times even in the absence of suppuration. This may be septic absorption or perhaps in some way due to the growth. This has occasionally been noted in uncomplicated growths elsewhere in the colon.

Three cases had the complication of suppuration around the growth. In one of these the onset was as a subacute appendicitis, but after draining the abscess for some weeks a firm swelling became palpable and later it fungated through the sinus. There were no symptoms of obstruction. In the second case there was a large abscess which had probably been present for some weeks. In the third case there was a very small collection of pus around the growth, not sufficient to cause adhesions which prevented removal. The similarity in such cases to appendicitis is marked, as it may be in uncomplicated cases of cæcal cancer.

Continued irritation as a possible etiological factor could not be asserted to be present in a single case. It may be thought that chronic constipation and an overloaded cæcum, stercoral ulceration, or a chronic appendicitis might have some influence, as irritation seems to play a part in some cases of cancer elsewhere. Chronic appendicitis seems not infrequently to have been present in many cases of carcinoma of the appendix. In not a single instance was it present in this series. Chronic constipation was nearly always absent. In only two cases have I noted it. Judging from the frequency which many writers of great experience regard cancer of the stomach to be preceded by a simple ulcer it might be thought that a similar condition would prevail in the rest doctrines of evolution. I have endeavoured to explain how a certain intimacy of association between intermediary and definitive host is essential for the parasites employing them, and how this association must not be confined exclusively, as regards either host or intermediary, to a single individual of each or either.

The protozoa and possibly the nematodes acknowledge, in my opinion, a very remote ancestry—that is to say, they became parasitic very early in the growth of the phylogenetic tree. There are other parasites, however, which manifestly must have adopted the parasitic habit very much later in the history of the animal kingdom. Certain insects, which probably from the beginning were closely associated with vertebrates and lived on the juices of these vertebrates, finding that they no longer required their wings, gradually dropped these wings and permanently attached themselves to their vertebrate food source. Such are many of the hemipterous and apterous insects, lice, &c. Similarly the ancestors of the acari, of some of the ticks, and other ectozoa have gradually fallen into complete or partial parasitic habits; certain bugs and ticks are even at the present day in process of acquiring this habit. I have no doubt that, as with the modern mosquitoes, ticks, and bugs, the ancestors of the existing huge ectozoal fauna of man and other vertebrates fostered parasites which they possessed in common with their respective vertebrate associates. What, you may ask, has become of these parasites? Have they failed to do what other parasites and the hosts of other parasites have succeeded in doing; have they failed to adapt themselves to their gradually changing environment? And if they have succeeded in adapting themselves how did they manage to overcome certain obvious difficulties, for example, that which I have indicated as being so necessary to such parasites, the go-between habit of at least one of the hosts, that necessity which is so efficiently subserved in the case of the malaria parasite by the mosquito?

I believe that this has been effected by a process of reversion, the asexual form of the parasite gradually re-acquiring, for purposes of propagation, the capacity and habit of direct passage from vertebrate to vertebrate, the necessity for sexual reinvigoration from time to time being still subserved by the ectozoal descendant of an originally free insect or other arthropod.

That is how I would explain the apparent absence of an insect intermediary in the trypanosome disease, dourine. Some apterous, hemipterous, or semi-parasitic insect phylogenetically allied to the tsetse flies is its intermediary. This insect has not been found, probably because it has not been looked for in the proper way.

I hold, therefore, that the existence of a sexual phase in the sleeping sickness trypanosome, *Trypanosoma gambiense*, and other trypanosomes is more than probable, that it has not been disproved, and that the argument founded on the natural direct communicability of dourine in the apparent absence of an insect intermediary for its germ, *Trypanosoma equiperdum*, is not valid, and that the evidence hitherto adduced is distinctly in favour of a law to the effect that blood-haunting protozoa having arthropod vectors require, and make use of, these vectors for necessary sexual development. Why the sexual stage of these parasites is passed in the arthropod and not in the vertebrate I cannot explain, any more than I can explain the contrary arrangement which obtains in the blood-haunting nematodes, the sexual stage in their case being passed in the vertebrate host, the asexual in the insect.

I have no doubt, while listening to these remarks, it has occurred to some of you, as it has often occurred to me, that the principles I have endeavoured to express have a wider application than that which I have directly indicated, that our disease germs and our ectozoa—insignificant though the latter appear to be—are correlated more frequently than is generally suspected, that, in fact, there is a necessary relationship between them. Indeed, in some instances we are beginning to find this to be the case. I have no doubt some of you dimly perceive that the whole of this subject, which recent studies in tropical medicine have done so much to develop, may have important practical bearings, that it is not an exclusively tropical one, and that in the near future it may find an application in the explanation of the pathogenesis and, therefore, an application in the prevention of many diseases of temperate as well as of tropical climates. It is a tempting theme to enlarge on. I must forbear. I feel I have already been sufficiently hypothetical. Perhaps some future Huxley lecturer will atone for my sins in this respect and supply the facts which, I acknowledge, are still lacking fully to establish the several hypotheses I have endeavoured to express.

THE TREATMENT OF INOPERABLE CANCER.[1]

By HENRY MORRIS, M.A., M.B. LOND.,
PRESIDENT OF THE ROYAL COLLEGE OF SURGEONS OF ENGLAND; CONSULTING SURGEON TO, AND EMERITUS LECTURER ON SURGERY AT, THE MIDDLESEX HOSPITAL, LONDON.

WHEN the Central Committee of the International Society of Surgery honoured me in March, 1906, by asking me to read a paper at the Congress in 1908 on the treatment of inoperable cancer they were, I believe, aware that I had opened a discussion on the same subject at the meeting of the British Medical Association at Manchester in August, 1902. It is now, as I write, about five and a half years since that discussion took place, and with but little exception the question stands to-day much as it did then. Increased experience and the mere lapse of time have enabled some of the methods then under consideration to be more justly appraised, and certain others which have since then been claimed to be cancer cures have been brought forward, but there has been, unfortunately, no definite advance towards the discovery of a reliable cure. If, therefore, I borrow somewhat freely from my former paper, it is on the old Greek principle that having once said what one wished to say, one can hardly say it twice, δὶς δὲ οὐκ ἐνδέχεται, except by repeating one's own words.

I will begin by quoting verbatim the definition I gave in 1902 of the meaning of the terms the "treatment of inoperable cancer."

"The term 'cancer' is used in a general sense to include all forms of malignant new growths, and therefore embraces rodent ulcer, sarcoma, and lympho-sarcoma, and endothelioma as well as epithelioma and other varieties of carcinoma. The term 'inoperable' means that the disease cannot be entirely eradicated, or permanent immunity hoped for, by a cutting operation, or by the actual cautery, or any escharotic aiding the knife. It does not imply that malignant disease is of constitutional as distinct from local origin and that as such it is ineradicable. On the contrary, I take it for granted that cancer is at first, and so far as rodent cancer is concerned throughout, a local disease. But even on this view there are four groups of inoperable cases. They are: (1) primary cancer affecting inaccessible parts and organs; (2) primary cancer which though originating in an accessible part or organ of the body has been allowed to extend beyond the limits within which an operation is prudent and complete removal possible; (3) certain cases of acute diffuse carcinoma and very rapidly growing or widely infiltrating new growths of exceptionally virulent character; and (4) recurrent cancer, where the disease has recurred in multiple metastatic foci or in parts beyond the limits of removal. Many of the cases included in these groups are submitted to operation for the purpose of palliating symptoms or prolonging life. Hence the term 'treatment' as applied to inoperable cancer means one of two things: (1) the employment of remedies and methods other than the knife, to cure, ameliorate, or retard the disease, as well as to prevent relapses after its removal; or (2) the employment of the knife to give relief from pain, to prolong life, to restore function, and otherwise to make the patient's condition more tolerable."

PALLIATIVE OPERATIONS.

In a paper which is intended merely to introduce a discussion it is of course quite impossible to consider all the many palliative operations which are resorted to in cancer of the various organs and regions of the body. Only the principal methods employed to combat cancer in the organs and parts most commonly affected will be referred to and those only with regard to their reputed or accredited beneficial results.

[1] A paper read at the International Surgical Congress at Brussels on Sept. 24th, 1908.

of bowel farther and farther away from the site of obstruction. Well-marked peristalsis of small and large intestine was seen showing that whatever may have been the previous history the obstruction had been present for some time. The diagnosis of the site of the obstruction when the latter was complete with well-marked distension and peristalsis was in the absence of any palpable tumour impossible. A tumour in such cases was felt in five cases only.

Suppuration or [illegible] occurred in 12 cases. In all except one [illegible] was in the peritoneal cavity. In this the growth was at the pelvic colon adherent in the iliac fossa. A large abscess was present in the iliac fossa behind the peritoneum and tracking upwards towards the lumbar region; this was traced directly to the growth. There are three ways in which the peritoneum may become infected:—

1. *An ulcer in the cæcum may perforate.* There were five cases in this series. In three this occurred during the period of complete obstruction. In each the peritonitis was diffused. The growth was in the pelvic colon in two and at the splenic flexure in one of these. In the two cases, although chronic obstruction had been present for some time, it had not terminated acutely. These growths were in the pelvic colon. In both the cæcum was much distended, as shown at operation. In one, in addition, a perforation had occurred just above the growth and the abscess had travelled up along the colon and formed a collection of pus under the left diaphragm around the spleen, with infection of the pleura.

2. In six cases the infection occurred *through the base of the growth.* In three of these the peritonitis was diffused. In only one of these three did the perforation occur when the obstruction was complete. In three a localised abscess formed around the growth, slowly and insidiously without any acute onset and not during the period of complete obstruction. In five the growth was in the pelvic colon and one at the splenic flexure.

3. In one case only did perforation of a stercoral ulcer above the growth occur and cause diffuse peritonitis. This occurred in the period of complete obstruction. The growth was in the pelvic colon.

In two cases there was an intestinal fistula. In both a growth in the pelvic colon had communicated with the bladder.

The occasions when it was feasible to perform a radical operation were comparatively few. In tabular form with contra-indications this is shown as follows:—

—	Removal possible.	Removal impossible.
Hepatic flexure.	2 cases. 1 was removed; the second complete obstruction, unsuccessful colostomy.	3 cases, adhesions posteriorly.
Transverse colon.	2 cases; only 1 operated upon.	1 case, fixed posteriorly.
The splenic flexure.	2 cases, both removed; 1 successful; 1 succumbed from obstruction due to adhesions.	8 cases. 1 had secondary deposit in liver, locally removeable; 1 secondary ovary and adherent to parietes, 2 diffusely adherent to small intestine; 2 fixed to parietes, 1 perforative peritonitis; 1 localised abscess.
Pelvic colon.	13 cases; 10 excised: eight successful, two deaths. 3 completely obstructed, unsuccessful colostomy.	24 cases. 1 case had diffusion of growth over the peritoneum, extensive glands and secondary liver; 1 secondary ovaries and liver; 2 adhesions and secondary liver, 6 adherent to pelvic brim or sacrum; 4 adherent to pelvis and small gut; 10 cases complicated by perforative peritonitis or localised suppuration.

In only 19 out of 55 cases would it have been possible to remove the growth. Adhesions to surrounding structures were the great barrier. Secondary visceral deposits were once of themselves the only cause. Glands was a possible cause in one case of a growth in the transverse colon and in three of the growths of the pelvic colon would have prevented removal, but there were other contra-indications also present in these three cases. I have considered that in all cases where perforation or localised suppuration has occurred removal was contra-indicated. It is possible that if some of the cases of perforation of the cæcum had been operated upon before the catastrophe removal might have been performed.

Results of Operation.

1. *Excision.*—One case of excision of the hepatic flexure is quite recent. One of resection of the transverse colon remained in perfect health for three years. He then developed acute obstruction from adhesions and died. There was not a trace of growth in the abdomen. One case of excision of the splenic flexure is well, six years after. Of eight resections of the pelvic colon only seven can be traced. One recurred in the glands and died nine months after the operation. A second recurred in the glands after the primary operation; these were excised and he was well four years afterwards. The remaining five are well at intervals of ten months, 14 months, 17 months, two years and ten months, and three years.

2. *Anastomosis.*—Two cases of growths in the hepatic flexure lived four and 13 months respectively. One case of the transverse colon lived eight months. One case of the splenic flexure (this was associated with local suppuration) lived four months, and the second nine months.

Harley-street, W.

Clinical Notes:
MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

A NEW COMBINATION ELECTRIC WAVE APPARATUS AND ITS THERAPEUTIC VALUE.

By W. Stansfield, M.R.C.S. Eng., L.R.C.P. Lond.,
LATE HOUSE SURGEON, MANCHESTER ROYAL INFIRMARY,
AND
Alfred Johnson, M.R.C.S. Eng., L.R.C.P. Lond.

WE have been impressed by the results obtained by the use of what we believe to be a new modification of the three-phase electrical current in the treatment of atony of muscular tissue, either striped or unstriped. The instrument which we have recently clinically tested is known as the Lloyd combination wave apparatus; it is simple and inexpensive. A four-volt accumulator drives a motor generator with three commutators producing three currents; there is a device of a shunt across the armature for the production of three minor currents. These three major and minor currents, all of sine nature, are led to three ordinary induction coils, from which wires are connected to three-pad electrodes. An electrical brake on the motor and a rheostat render the speed of the contractions well under control. In treatment of atony of the alimentary canal one pad is placed in the lumbar or sacral region and the remaining two on the abdominal wall. The three minor waves seem to modify the effect of the three major waves as seen in the ordinary three-phase apparatus, and the effect is to produce a painless contraction of the muscles.

We have been using this apparatus for nearly a year and the following are notes of a few cases:—

CASE 1.—A. B., a slight pale lady with a congenitally small liver, never remembered having her bowels opened naturally, her motions always being of a very light colour. She was ordered an aperient strong enough to produce one motion a day and her diet was regulated. The three electrodes were used as described, the apparatus started in a manner to produce slow contraction, and with the two front pads the abdomen was massaged. After a fortnight's daily treatment of 10 to 15 minutes at a time the colour of the motions improved and she required less aperients. Aperients were entirely stopped at the end of three weeks, and the treatment was continued another week. Some three months later there had been no relapse.

CASE 2.—C. D., a little girl, aged eight years, pale, weak, and undersized, had not had her bowels opened without assistance since she was six months old. She was treated only 21 times in two months, at the end of which she was taking very little medicine and often doing without, the electric treatment sufficing.

CASE 3.—E. F., a middle-aged lady, had suffered with constipation for two years, her abdomen being lax and flabby with a loaded colon. She was treated daily for three weeks, also with gradually decreasing doses of aperients. She was entirely relieved at the end of this time, her spirits and appetite better, her figure much improved, and she was stronger in every [illegible].

CASE 4.—G. H. [illegible] She had been un[illegible] and had received no benefit. He [illegible] emptying of the stomach of its acid products and to the failure of the neutralisation of these products by the bile and pancreatic juice. This failure is caused by the absence from the duodenum of the hydrochloric acid which stimulates both the bile and the pancreatic juice to flow.

Rydygier has recently pointed out some of the drawbacks of gastro-jejunostomy.[3] M. M. Portis of Chicago,[4] in protesting against the "appalling increase in the number of gastro-enterostomies in the past few years," refers to the numerous recorded cases of ulcer of the jejunum following gastro-enterostomy and to the persistence of symptoms and sometimes the fatal termination which are consequences of the operation.

Other complications which gastro-enterostomy does not prevent, even if it does not assist in promoting, are the breaking down of the growth, hæmorrhages from the growth or from a recently formed jejunal ulcer, toxæmia or intoxication from fermentation products, and post-operative pulmonary infarcts and septic pulmonary complications which are far from uncommon in gastric cases.

Gastro-jejunostomy ought not to be proposed when cachexia and emaciation are very pronounced, when patients are seen very late, or when the growth does not cause obstruction of the pylorus or stasis of the contents of the stomach.

Mikulicz gives 9 per cent. as the operative mortality of simple laparotomy in the late stages of the disease. If cancer of the stomach was diagnosed early and operated upon as soon as recognised then pylorectomy and partial gastrectomy might entirely do away with gastro-enterostomy for carcinoma. The immediate mortality of partial gastrectomy in suitable and early cases is not greater than that of gastro-jejunostomy, whilst the comfort and relief from it are more permanent, and the prolongation of life, even if recurrence takes place, is stated by Jacobson[5] to be longer by one year.

Willis G. Macdonald of Albany[6] collected 43 cases of pylorectomy for carcinoma of the stomach in which the patients were living without recurrence three years after the operation; and there were patients in this group who were alive ten years after the primary operation without symptoms of recurrence.

In *rectal cancer* the proportion of cases which from their commencement are either unsuitable for excision, or have become so when the patient is seen for the first time by a surgeon, may be estimated from the figures given in the fifth edition of Harrison Cripps's book on "Cancer of the Rectum" just published. Of 380 cases in his own practice 283 were deemed suitable for operation and 97 unsuitable. Of 228 cases actually operated upon 85 were treated by excision and 143 by colotomy. 55 patients refused operation. Thus somewhat more than 74 per cent. of patients with cancer of the rectum either do not seek a surgeon's advice before it is too late or else have the disease in such a position as not to allow of any chance of cure by operation. Of the 85 cases of excision the disease recurred in 33, and in 15 of these 33 colotomy was subsequently performed.

Colotomy, besides entirely obviating the risk of death from intestinal obstruction, affords relief from many of the usual symptoms of rectal cancer and retards the rate of increase of the growth. Compared with the majority of cases in which the disease is left to take its natural course those persons on whom colotomy has been performed as a rule live longer and have a less uncomfortable existence. Cripps was able to follow up the histories of 97 of the patients upon whom he had performed colotomy and found that 62 lived from 12 months to three years, 14 others lived upwards of three years, and one of the 14 survived for eight years and three months.

The prospects from colotomy are much better when the operation is done before complete obstruction sets in. The mortality of the operation in 123 cases in which the operation was performed before obstruction occurred was only 4·6 per cent., whereas it was 55 per cent. in 20 cases done after obstruction had commenced. Happily, of late years colotomy has been resorted to at a much earlier stage than was the practice formerly.

From a glance at the tables of colotomy operations for cancer which were presented at the International Medical Congress at Copenhagen in 1884 by Mr. Thomas Bryant, Professor C. Studsgard, and myself[7] it will be seen how large a proportion of the colotomies up to that time were done only after the occurrence of complete obstruction. Twenty-four years ago colotomy was not firmly established or generally accepted, even in England, as an operation to be recommended and was, I believe, very rarely if at all practised in Germany and France. But subsequent experience of its efficacy as a palliative operation, together with the diminished and diminishing dread of surgical operations generally, have led the profession to recommend, and patients to submit to, colotomy at a much earlier stage instead of postponing it until days, and often many days, after complete obstruction had set in.

As substitute operations for colotomy when the disease is close to the anus linear proctotomy and erasion of the growth have sometimes proved to be temporarily beneficial. The median rectotomy as practised by the late M. Verneuil of Paris, and the lateral rectotomy followed by the use of Paquelin's cautery as recommended by the late Mr. John Marshall of London are now rarely if ever employed. In cases in which simple palliative means alone are permitted or available much benefit is often derived from the regulated *injection of an antiseptic solution through a large-sized* catheter or a small-sized tube passed along the bowel and beyond the growth.

The line of demarcation between operable and inoperable *cancers of the uterus* has recently undergone a change. Writing in 1902 I referred to the great improvements in the technique of vaginal hysterectomy, to the diminished death-rate of the operation, and to the freedom of the patients who had been submitted to it from dysmenorrhœa, hæmatometra, hæmatosalpinx and the other sequelæ of supravaginal amputation of the cervix. But having said this much I went on to remark: "No radical operation, however, is worth performing when the disease extends beyond the limits of the uterus into the connective tissue about the cervix, or into the utero-sacral or broad ligaments, or when the vagina is extensively involved. In such cases prolonged immunity, to say nothing of permanent benefit from an operation, is out of the question." To-day, Wertheim's method of operating has become better known and has in consequence brought many cases into the operable list which previously had been considered to be inoperable. The Vienna professor's operation has also by some gynæcologists been employed in cases which others consider well suitable for vaginal hysterectomy. By Wertheim's operation extensions of disease into the broad and the utero-sacral ligaments, affected glands lying in the fork between the external and internal iliac arteries, nodules of new growth outlying an inch or more from the cervix uteri, as well as disease in the upper part of the vagina, can be removed. The operation is unquestionably a very difficult and severe one, but Dr. Arthur Lewers[8] of the London Hospital, who has been employing it since 1905 in cases too advanced for vaginal hysterectomy, thinks well of the results he has obtained by it.

In cases of fungating carcinoma of the uterus and also of the anus and rectum the use of the curette followed by the application of zinc chloride either by means of pledgets of cotton wool soaked in a strong solution or by applying the solid salt itself to the margins and raw surfaces of the diseased area, which I frequently employed in my wards in the Middlesex Hospital, has met with increasing favour. Otto von Herff[9] is strongly in favour of its use in uterine carcinoma but is opposed to its application in endometritis. Gellhorn[10] follows up curetting with the application of acetone. Formalin he finds too painful when concentrated and without action when diluted. Curetting and the extensive use of the thermo-cautery or of concentrated carbolic acid[11] also give very good results. But with each of these methods the effects are only temporary and the procedure needs to be repeated at varying intervals.

In certain cases of *mammary carcinoma* the breast should be removed for palliative purposes even when there are present affected and irremovable glands and widespread

The Substance of Faith Allied with Science: A Catechism for Parents and Teachers. By Sir OLIVER LODGE, F.R.S. London: Methuen and Co. Pp. 135. Price 2*s.* net.

To afford instruction in religious principles to children in such a manner as to be consonant with the knowledge which they acquire of science in the course of their secular education is a task which must of necessity present difficulties to parents and even to teachers owing to the lack of the special knowledge and experience required to reconcile apparent discrepancies which may present stumbling-blocks to the keen intelligence of the thoughtful child. Sir Oliver Lodge, fearful "lest the nation, in despair of a happier settlement, should consent to a system of compulsory secularism," endeavours in this small catechism to outline a scheme of instruction whereby the fundamental principles of religious belief shorn of sectarian or doctrinal complexities may be expressed in terms which are not in conflict with existing knowledge. In illustration the facts of nature as seen around us are employed and the essential truths of religion and science are thus taught in relation to one another, with the object of formulating a creed. The nature of man is first outlined, and the meaning of existence, of ancestry, of the general principle of evolution, and the development of man from lower forms of life is explained. Next the development of conscience and its meaning are traced, then the sense of responsibility and its relation to character and will, thence the duty of man to assist his fellows, to develop the higher phases of his nature, and to strive towards betterment is deduced. Good and evil are defined and their place in the scheme of nature is indicated and the means whereby to know good from evil are detailed. In defining evil the fact that it is not absolute but has reference to a standard of attainment is clearly emphasised, and as a corollary it is pointed out that evil is a necessary consequence of a rise in the scale of moral existence, and that, therefore, sin is the deliberate choice of evil where the good is possible. The general principle of Immanence or the Intelligence everywhere indicated in all the processes of nature is then developed:—

> "Earth's crammed with Heaven,
> And every common bush afire with God."

This, indeed, is the whole purpose of the book—to inculcate the lesson that the controlling Thought and Purpose is immanent in everything. Man's higher faculties, with special reference to the spiritual side of his nature, are next considered and in connexion therewith the idea of a beneficent Deity is evolved, One who is willing to help man in his struggle to higher things. Sir Oliver Lodge gives on p. 96 a creed expressing in simple words the general principles which he has illustrated. The subsequent sections are developments of some of the principles enunciated in this creed, including the conceptions of eternal life, of prayer, and of the Kingdom of Heaven.

The book is written in simple style, is throughout reverent, and inculcates Christian doctrines in a way that must commend it to all who are concerned in the religious instruction of children.

Manual of Midwifery. By T. W. EDEN, M.D., C.M. Edin., F.R.C.P. Lond., F.R.C.S. Edin., Obstetric Physician, Charing Cross Hospital. New (second) edition. With 42 plates and 236 other illustrations. London: J. and A. Churchill. 1908. Pp. 555. Price 12*s.* 6*d.* net.

THE early appearance of a second edition of this book is a proof of the favour with which it has been received by students and practitioners, a favour which is well deserved. Dr. Eden has carried out a careful revision of this edition and by placing a number of the more important illustrations on separate plates he has succeeded in increasing the amount of letterpress without increasing the size of the volume. Several of the chapters have been partly rewritten and additions have been made, more especially to those on the sections dealing with abdominal palpation, the puerperium, and infant feeding, while a section has been added on premature rupture of the membranes, the consideration of which had been omitted in the first edition. A number of new illustrations, many of them original, have been introduced. The difficulty which the placenta seems to present to artists as a subject for illustration is well shown by Figs. 22 and 23, both of which are decidedly poor. The book as a whole is practically unaltered and forms a most excellent and trustworthy text-book, quite the best of its kind in the English language. Naturally we do not agree with all that the author says, nor do we think that there are not points in the book which would bear further emendation in future editions.

The importance of abdominal palpation is more fully recognised in the present edition than it was in the first and a good account of it is now given. The question of the exact size of the uterus at different periods of pregnancy always seems to be a stumbling block to the writers of text-books. Possibly this is due to the fact that different authors when discussing the height of the fundus uteri at the different months of pregnancy are not particular enough always to consider the subject with the body in the same position; thus some of the levels are measured with the patient standing upright and others with the body lying on the back. Dr. Eden tells us that measurements of the height of the fundus of the uterus above the pubes are somewhat fallacious, and in this statement we quite agree unless the conditions under which they are taken are clearly stated; at the same time, we think that the method of describing the level of the upper border of the uterus in relation to the position of the umbilicus is even more fallacious and misleading. We see no object in the author's recommendation to shift the grasp of the hand to the shank of the axis-traction forceps instead of continuing to pull on the traction rods, the correct method, when the head of the child is near the outlet of the pelvis; nor do we think that as a rule much is to be gained by removing the forceps before the delivery of the head. It is a pity that in the excellent plates representing delivery by the forceps the hands are not represented as covered by rubber gloves, possibly a counsel of perfection but none the less often an important precaution. In the treatment of ophthalmia neonatorum it would be better to give the exact strength of the solution of silver nitrate or protargol to be instilled into the eyes.

In spite of these minor criticisms we are of opinion that this is a most trustworthy book and we congratulate Dr. Eden on the success which it has attained.

A Manual of the Practice of Medicine. By FREDERICK TAYLOR, M.D. Lond., F.R.C.P. Lond., Consulting Physician to Guy's Hospital; Consulting Physician to the Evelina Hospital for Sick Children; Physician to the Seamen's Hospital, Greenwich. Eighth edition. London: J. and A. Churchill. 1908. Pp. 1111. Price 16*s.* net.

THIS text-book is too well known to require any words of introduction from us; suffice it to say that Dr. Taylor has succeeded in offering a short yet complete account of the present state of medical practice which will be useful to students and practitioners. He has devoted most attention to the description of symptoms, to diagnosis, to prognosis, and to treatment, rightly feeling that they are the divisions of the subject which best answer to the idea of practice. In the preparation of the present edition every part of the pylorectomy, whereas now too many of these patients drift on and are subjected at a late stage to the miseries preceding and following gastro-jejunostomy. So also in cancer of the larynx if the diagnosis were made early many patients would be cured by thyrotomy who are now submitted to the mutilating effects of total laryngectomy.

One of the greatest boons to be expected from the early recognition and early, and thereby curative, operative treatment of malignant disease would be the diminution in number and severity of the palliative operations now performed. In the course of my remarks I have already raised the doubt whether life after some of these operations is worth having.

The question of the expediency of performing operations when the duration of the comfort and improvement they afford is only a few weeks or a few months, may be considered an open one. But for my own part I entirely agree with Sir Felix Semon that "it is one thing to perform a brilliant operation, and thereby to prolong a patient's life, it is another to see him a few months afterwards dragging on a most pitiful existence." There ought to be a chance, even if remote, of the patient operated upon remaining free from the disease, or at any rate from the pain and other worst symptoms of the disease, if he submits to a serious operation, instead of a prospect of certain death within a few months under great suffering. In operations purely palliative in aim, such as gastro-jejunostomy, for example, this chance is not given. There is not the remotest hope or prospect of non-recurrence, because the disease is not removed; whilst certain death with great suffering, even though it may not come till after a spell of some few months of comparative health and comfort, stares the patient in the face throughout. Probably each of us has known instances, however, in which circumstances connected with the patient and his family have made it desirable, if not well-nigh imperative, to prolong life to its utmost limits—circumstances which have made the martyrdom of living worthy of the heroism which can face such an existence. This apart, the value of a palliative operation must be measured by its efficacy in securing ease and comfort to a patient whilst he is awaiting his end. I am disposed to think that some who speak so enthusiastically in favour of those operations for advanced cancer, of the stomach for instance, can hardly have been witnesses of the last stages of the patients who have undergone them. Nor is it warrantable to assume that because an abdominal tumour has entirely disappeared after the performance of a gastro-jejunostomy its doing so was an effect of the operation. Other cases are on record of cancerous tumours disappearing after cœliotomy, and a surgeon writing on epithelioma of the penis mentions a case in which the disease entirely disappeared in a man "who refusing operation eloped." In other cases in which no operation has been done tumours have vanished spontaneously. If we are to give credit to the gastro-jejunostomy in the one case how can we withhold it from the cœliotomy in the other, or from "elopement" in the third case; and are we to quote Proverbs xx. 3 with regard to spontaneously vanishing tumours and attribute their disappearance to not "meddling"?

OTHER METHODS OF TREATMENT.

I pass over the treatment by Finsen light, the Röntgen rays, and by radium, which are to form the subject of a separate discussion at this meeting. Neither shall I on this occasion refer to such local applications as strong liquid ammonia, cancroin, calcium carbide, methylene-blue, formalin, nosophen, corrosive sublimate; nor to the injection of cinnamate of sodium, of alcohol, acetic acid, gelatine, snake poison, turpentine; nor to the freezing process by means of carbonic acid described by Professor Homitz. Nor shall I stop to speak of the entirely negative results obtained after fair trials from alder leaves, violet leaves, marigold ointment, or molasses.

I have nothing new to say about thyroid feeding or Dr. J. H. Webb's treatment by injections of soap. Sir George Beatson's opinion of thyroid extract in cases of carcinoma generally is still favourable, provided it is given in small doses and is carefully watched. He administers it after ordinary operations for removal of carcinoma, continuing its use for long periods and he thinks with advantage.

The treatment by inoculation with a vaccine prepared from the micrococcus neoformans of Doyen, th[illegible] some to have been successful in certain cases, has been generally disappointing. Doyen's serum treatment is now, I believe almost universally, deemed to be of no value. Neither the vaccine nor the serum treatment with Otto Schmidt's cancer parasite, nor Wlaeff's serum obtained by inoculating asses with yeast parasites derived from carcinoma, has been found useful.

Schmidt's treatment by means of the injection of the sterilised "killed culture" was tried upon several cases in the cancer wards of the Middlesex Hospital in 1903–04 without any benefit whatever following.

The treatment by electric currents of high voltage and high frequency which in 1902 Dr. James Allan and others thought would prove to be of important therapeutic value in inoperable cancer has been of late actively advocated by Keating Hart. The treatment was tried in the cancer wards of the Middlesex Hospital by a brush discharge both with and without sparking, and was found to have a decided local influence upon an ulcerated surface whether simple or malignant. The ulcer shows a decided tendency to diminish, fungating areas sometimes break down, discharges decrease and become thin and less offensive. The patients are benefited in a general way and show increased tone and nutrition. But no successes attended by the disappearance of the growths such as were obtained by Dr. Allan could be recorded, and the treatment after fair trial in the cancer wing of the hospital was abandoned.

Keating Hart's method consists in removing with the knife the cancer tissue acted upon by exposure for from 5, 10, to over 40 minutes to the strongest possible "lightning spark pencil" at the distance of two to four centimetres and with frequent changing of the area exposed. After the cancerous tissue has been extirpated the wound surface is again exposed to "fulguration." The patient is anæsthetised all the time as the treatment is so painful. Czerny[17] has recently reported on Keating Hart's method after trial in 35 cases, only three of which were "inoperable," two being small epitheliomata on the inside of the cheek and the third a small rodent on the nose. These three cases were essentially cured by an exposure of 10 to 15 minutes' "fulguration," followed by scraping. They could all three have been cured by other methods, but not, adds Czerny, with so little inconvenience or disfigurement. The other cases were all "inoperable" and no cure was obtained. Pain associated with septic degeneration in growths is relieved, but the growth and sepsis return. Hæmorrhage can certainly be controlled by the method. Czerny considers his experience is of too brief duration to permit him to confirm the magnificent cures in inoperable cancer reported by Keating Hart, or to doubt them.

In the treatment of sarcoma I have continued to use the mixed toxins of the streptococcus of erysipelas and the bacillus prodigiosus—Coley's fluid; but I have no definite beneficial results to report. In some instances I have thought there has been improvement, as shown by delayed growth, lessened pain, and diminished tension, but in no case cure. I am at the present time using the standardised preparation proposed by Dr. Martha Tracy[18] on a case of recurrent sarcoma of the upper jaw. There have been relief from pain and some subsidence in the size of the growth, but what the ultimate result will be I cannot say.[19]

TRYPSIN TREATMENT.

The bacteriological study of malignant new growths having been barren of positive etiological or therapeutical results of general application, it was natural that other lines of research should be followed. With a return to the search for the explanation of cancer within the body itself, attention became directed to the weapons with which the body defends itself against obnoxious elements, or which are employed by parts of, the body when they require to live and grow, or with which to satisfy less urgent needs at the expense of other parts of the organism as a whole. According to prevailing conceptions these weapons are the ferments and their allies the "hormones" of Starling.

The important part played by intracellular digestion (phagocytosis) in the defence of the body has received

occurred in 1·7 per cent.; poor and fair results—i.e., vision of less than 6/60—in 6·2 per cent. No details are given of the vision in the results considered good. The remainder of the work deals with after-complications and the treatment of complicated and soft cataracts. There is one phrase—"vitreous tension"—which occurs repeatedly in the book. It implies the tendency to prolapse of vitreous which is found in a certain fairly well-defined group of cases. The condition is one so entirely different from any to which the term tension is usually applied that the designation is undesirable and should be replaced by some other having greater regard for pathological accuracy.

Summing up, we may reiterate the opinion expressed at the commencement of this review. It is a book to be read and pondered over by experienced ophthalmologists. It is not suitable for the beginner who will be unnecessarily discouraged by it. Even the expert practising in more advantageous circumstances will be well advised to refrain from taking every statement *au pied de la lettre* but he cannot fail to find much which will prove of value.

The Theory of Ions: A Consideration of its Place in Biology and Therapeutics. By WILLIAM TIBBLES, M.D. Chicago, LL.D., M.R.C.S. Eng. London: Rebman, Limited. 1908. Pp 131. Price 2*s.* 6*d.*

WE may not agree with much that the author says in regard to the importance of the position occupied by the theory of ions, but we are bound to admit that he has succeeded in collecting an amount of information on the subject which brought together in the compass of the small volume before us will be distinctly helpful to those who are anxious to keep pace with modern ideas on those questions which bear upon vital phenomena.

In the author's view the ionisation of materials plays a rôle in the evolution of the living from non-living substances. The continuous adjustment of the internal relations of materials to the external relations is, he suggests, brought about by the ionisation of matter, the transformation of energy, and the definite combination of these heterogeneous changes both simultaneous and successive; and these, in correspondence with external co-existences and consequences, result in the development of the dead into the living, the inorganic into the organic. As far as human faculty can interpret things there would appear to be strong reason for believing that the ions are capable of appearing at one time as one substance and at another time as another substance—in a word, that the ion can serve as both a constructive and destructive agent. Ionisation thus takes place in living structures and the presence and activity of ions would seem to be essential in biological processes. There are chemists, of course, who reject this view, which, after all, is based on physical conceptions rather than chemical. They may, perhaps, be jealous of the claims of their science, but as Dr. J. S. Haldane said in his admirable address in the Physiological Section of the recent meeting of the British Association for the Advancement of Science at Dublin, while we have accumulating knowledge as to the physical and chemical sources and the ultimate destiny of the material and energy passing through the body we have an equally rapidly accumulating knowledge of an apparently teleological ordering of this material and energy, and for this teleological ordering we are at a loss for physico-chemical explanations. The spectre of vitalism, he added, meets us at every turn thinly disguised under such names as "cell autonomy," "vital processes," and so forth. The same argument, it seems to us, applies to ions. The theory of ions, in a word, expresses in a refined way the physico-chemical changes involved in biological processes. The theory is helpful inasmuch as it presents probably a more exact interpretation of biological phenomena. But there still remains the spectre of vitalism.

The theory of ions is also going to be helpful in the service of medical science in other directions, for it has already thrown some light on the fate and action of substances for medicinal purposes. To take one case and to quote Dr. Tibbles: "The effect of the salt is the algebraical sum of the effects of its individual ions. Anions and cations antagonise one another; cations precipitate, anions inhibit the precipitation in proportion to their power. All cations have certain physiological characters in common: they precipitate protein. They more or less increase the irritability of muscle and nerve; they excite intestinal activity and increase the blood pressure The anions have a solvent action on protein or, to speak more correctly, they inhibit the action of the cations in general. The physiological effect of the anions and their solvent action upon proteins increases through the scale from sulphate to sulphocyanate. The sulphates, citrates, and tartrates are protein precipitators, because the anion is associated with the over-balancing properties of the metallic ions, they are therefore cathartics. But in the nitrates, bromides, iodides, and sulphocyanates the anion has the predominating influence, the characteristic effect of which is sedative, attended by a decrease of blood pressure."

It is probable that subsequent investigation will prove that the theory of ions will eventually place many observed phenomena of medical science upon a more satisfactory scientific basis than hitherto, and the subject is therefore worthy of the attention of medical men, and a word of thanks is due to Dr. Tibbles for bringing together in this comparatively small volume the modern views upon the subject. We are surprised to find that he does not once mention the distinguished author of the theory. we refer to Michael Faraday.

LIBRARY TABLE.

A Short Practice of Midwifery for Nurses, as used in the Rotunda Hospital, Dublin, for the past Ten Years. By HENRY JELLETT, B.A., M.D. Dub., F R C.P. Irel, ex-Assistant Master, Rotunda Hospital. Third edition. London: J. and A. Churchill. 1908. Pp 463. Price 6*s* 6*d.* net.—*Infancy and Infant Rearing: an Introductory Manual.* By J. B. HELLIER, M D. Lond., Professor of Obstetrics in the University of Leeds. Second edition. London: Charles Griffin and Co 1908. Pp 164 Price 3*s* 6*d* net.—*Introduction to Infectious and Parasitic Diseases, including their Cause and Manner of Transmission* By MILLARD LANGFELD, A B., M B, Professor of Bacteriology and Clinical Medicine, John A. Creighton Medical College, Omaha. With an Introduction by LLEWELLYS F. BARKER, Professor of Medicine at the Johns Hopkins University. London: Rebman, Limited 1908. Pp. 260. Price 5*s.* 6*d* net.—*Practice of Medicine for Nurses* By GEORGE HOWARD HOXIE, A.M., M.D., Professor of Internal Medicine in the University of Kansas With a chapter on the Technic of Nursing by PEARL L. LAPTAD, Principal of the Training School for Nurses of the University of Kansas. London and Philadelphia: W. B. Saunders Company. 1908. Pp. 284. Price 6*s.* 6*d.* net.—Text-books intended for nurses are multiplying with almost the same rapidity as those for the use of medical students We presume this supply is created by a demand and that it reflects an increased standard of examination knowledge required from nurses in the course of their training. We are inclined to think that it would be better to expect them to rely firstly upon their ward experience and secondly upon notes of the lectures given them at their own school, carefully revised under some tutorial system, and in the last place upon knowledge gained from text-books. The temptation which these afford to cram a superficial smattering of a obtained painlessly, thus adding to the comfort of the patient in a manner not so easily attainable by other means. [illegible]ann reports satisfactory results of treating an extensive epithelioma involving the external ear and side of the neck by dusting with pancreatin in powder. The cleansing action of the trypsin proceeded till all dead and septic tissue was removed. Then the ingrowth of skin sufficed to protect the tumour tissue from its action at the margins. The deep extension of the tumour was not affected and the patient died 15 months after the treatment was begun but was made more comfortable during life by it. Whether the local application of trypsin in this way and adequately diluted has advantages which will enjoin its use externally in future remains to be seen.

Pending the time when as we hope the experimental study of cancer in animals will yield results of positive value in treatment, discursive controversies on the value of this or that alleged remedy, though to be regretted, must be expected. In the employment of remedies for the cure of cancer in man it is necessary that several years should elapse before finality in judgment can be attained. In the case of trypsin the results of experiments were invoked by Dr. Beard in support of his contentions. Two mice suffering from Jensen's carcinoma exhibited symptoms after the injection of two and a half minims of 1½ per cent. solution of trypsin, which Dr. Beard ascribed to intoxication by "the products of the tumour (an alcohol ?), as extracted and digested by the large dose of trypsin." The tumours were found to be in an advanced state of degeneration and necrosis. This appearance in the tumours would have been startling if any evidence had been advanced by an adequate number of control experiments showing that degeneration and necrosis did not occur independently of the treatment. As a matter of fact, it has been shown by Bashford, Murray, and Bowen that 90 per cent. of the tumours obtained by propagating Jensen's carcinoma exhibit very extensive necrosis; only a thin shell of healthy tissue may remain. These observers also treated with trypsin mice suffering from adeno-carcinoma mammæ, squamous-celled carcinoma, malignant adenoma and sarcoma in many series of experiments. In doing so they paid attention to any evidence of the symptoms of intoxication, the induction of necrotic degeneration and inhibition of growth, or of the specific action of trypsin on cancer tissue while sparing other tissues as described by Beard—but without being able to confirm his statements.

In the first place, active trypsin solutions are not without action on normal tissues. On the contrary, the solutions employed by them (even when diluted to the strength of 1 in 1000 and injected subcutaneously into mice in doses of 0·3 cubic centimetre to 0·5 cubic centimetre) produced great irritation and digestion of the overlying skin, so that in the space of one to three hours after injection the hair over the site of the fluid fell out and a large moist ulcer formed. Hence the doses of active trypsin which it is possible to give to mice subcutaneously without local destruction of tissue, and which are perhaps not inferior to the doses applied to the treatment of the human subject, are so infinitesimal that the absence of influence on the growth of tumours in mice so treated is not astonishing. To meet this objection other methods of application were sought. Intraperitoneal injection is also followed by digestion of the abdominal wall at the site where the fluid collects, the destruction of tissue tending to advance along the tract of the needle used to inject it. In their highest degree the consequences are speedy ulceration of the abdominal wall and escape of the intestines which appear to be not attacked. Both the above methods of administering trypsin in doses sufficiently great to be effective cause the greatest inconvenience to mice which suffer obviously from great pain and have to be quickly destroyed. It was found, however, that relatively enormous doses could be injected directly into the venous system and tolerated without any visible discomfort. A quantity of fluid almost equal to the total amount of blood in a mouse can be so injected, and, weight for weight of animal, doses of trypsin 300 times greater than those advised for administration to the human subject have been introduced into the circulation within a short space of time. The negative results on the growth of tumours bore out those obtained with subcutaneous injection.

The effect on tumour growth was tested in yet a third way. Mice were treated by the direct introduction of trypsin into the circulation before inoculation with a transplantable tumour and the treatment continued during the succeeding ten days following inoculation—i.e., till that time had elapsed within which the new tumours usually develop. The treatment was powerless to prevent the inoculated tumour tissue from "taking." The results were found to be quite independent of the amount of trypsin injected. The fact that the newly implanted tissue established itself disposes of the hypothetical objection that the other methods of testing trypsin had failed because the tumour cells had in course of treatment been able to immunise themselves against trypsin. The subsequent growth of the tumours in the mice which had been previously treated and continued to be treated with trypsin showed no differences from that of the tumours in normal animals not treated by trypsin.

Cavendish-square, W.

ON PREGNANCY, PARTURITION, AND THE PUERPERIUM AFTER VENTRIFIXATION (HYSTEROPEXIS HYPOGASTRIA).

BY SIR WILLIAM J. SINCLAIR, M.D. ABERD.,
PROFESSOR OF OBSTETRICS AND GYNÆCOLOGY, UNIVERSITY OF MANCHESTER.

IN a large proportion of the cases of old-standing chronic backward displacement of the uterus our ordinary methods of treatment do not give satisfactory results. When the body of the uterus has become considerably enlarged after backward displacement, or when even the slighter tubal and ovarian complications exist, what could be expected from more or less forcible turning forward of the body and the insertion of a pessary in the consulting-room? There is an element of levity in this method of dealing with a flexion producing symptoms.

When the patient can be persuaded to take to bed and remain as long as if she had to undergo an important operation some good can usually be done. The congestion of the body of the uterus can be relieved by tampons and douches, the amount of the relief being measured by the diminution in the tenderness to touch and by certain changes in the visible portion of the uterus. When the uterus has been restored by tampons almost or altogether to its normal position, then is the time for the introduction of a pessary. In some uncertain proportion of even old chronic cases this method of treatment gives sufficient relief to satisfy the patient, and a small number of cases are actually cured in time. As a general rule, it may be stated that the older the patient the more suitable the palliative treatment.

But in married women at the child-bearing time of life, and in many single women who cannot, or will not, lead restful lives, the treatment by mechanical support is highly unsatisfactory and something more must be done. Let me emphasise this fact: ventrifixation is suitable only for women at the child-bearing period of life; the atrophying uterus after the menopause requires other methods of treatment. Schultze's process may be dismissed with a word. It has never done positive harm to any patient of mine as far as I know, but upon the whole it has given no satisfaction. A blind manipulating of adhesions and displacements could hardly be considered the best attainable treatment. Massage is not a suitable method of treatment with a view to permanent cure in such ailments, and it is fortunately seldom mentioned in this country. Schücking's operation, and similar timid, futile, and yet obviously dangerous proceedings, I have never tried, and never will. Sänger,[1] in introducing his own operation, "Über Retrofixatio Colli Uteri Retroflexi," in 1891, was very sarcastic in his references to Schücking, and yet his own vaginal operation of shortening the sacro-uterine folds and partly closing the pouch of Douglas was neither thoroughly efficient nor permanent in such benefits as it conferred. Alexander's operation of shortening the round ligaments obtained great favour for many years and still holds its place as a valuable method of treatment in a certain limited class of cases. The eagerness with which it students and any attempt to assist them in understanding operations is well deserving of approval. This work is the English version of a work published in Germany in 1905; it consists of accounts of a number of the more important operations, illustrated by almost life-sized coloured plates, which show very clearly the structures concerned in each operation and the methods adopted. The utility of the book is greatly enlarged by plates showing the instruments employed in the operation. Some of the operations illustrated are tracheotomy, craniotomy, radical cure of inguinal hernia, ligature of the lingual artery, excision of the tongue, gastrostomy, gastro-enterostomy, and thyroidectomy. Many operations are of course omitted, but those which are given are well described and excellently illustrated, and the book will serve to give clear ideas on obscure subjects. For instance, many students find much difficulty in understanding the operation of gastro-enterostomy, but here it is clearly shown and should be readily understood by all. The English rendering is well carried out.

---

[1] M. Sänger: Operative Behandlung der Retrodeviationen des Uterus und Schucking'sche Vaginalligatur, Centralblatt fur Gynäkologie, 1892, No. 1.

A Manual of Diseases of the Eye. By CHARLES H. MAY, M.D., New York, and CLAUD WORTH, F.R.C.S. Eng., Assistant Surgeon, Royal London Ophthalmic Hospital, Moorfields. Second edition. London: Baillière, Tindall, and Cox. 1908. Pp. 400. Price 10*s.* 6*d.* net.—The second edition of this manual differs little from the first which we have already reviewed. Some passages have been transposed and a few new ones introduced. The illustration of excision of the lacrymal sac to which we took exception has been replaced by one less open to criticism. A paragraph has been inserted on the Morax-Axenfeld diplo-bacillus, removing the ambiguity which previously existed, though no stress is laid upon the peculiar distribution of the congestion of the conjunctiva and lid margins in the conjunctivitis arising from infection with this organism. The book therefore remains the same in all essentials—a good introduction to the subject but one which admits of considerable improvement.

Public Health Laboratory Work. By HENRY R. KENWOOD, M.B. Edin., D.P.H., F.C.S., with a Part Dealing with Public Health Bacteriological Work contributed by W. G. SAVAGE, M.D., B.Sc. Lond., D.P.H. Fourth edition. With illustrations. London: H. K. Lewis. 1908. Pp. 468. Price 10*s.* net.—Our appreciation of this work in notices of previous editions has been justified by events. We still think the book one of the best for the requirements of the student of public health, and more particularly as a guide on practical issues. He can read and adopt with confidence the methods outlined for the examination of water, sewage, air, food, and so forth. The section on food is necessarily short but it is sufficient for imparting a good general knowledge. The chapter on spirits, though brief, is instructive and to the point and shows that more attention than has hitherto been the case is being given to those constituents of spirits which differentiate patent-still from pot-still spirit. The sections dealing with bacteriological work in regard to questions of public health are contributed by Dr. Savage. These are also written in a way calculated to be of distinct service to the student in the public health laboratory. On the whole, we do not know of a better guide to the kind of laboratory work which has been called into being and demanded by modern methods of public health administration.

THE ST. PANCRAS SCHOOL FOR MOTHERS.—We have been asked to say that Mr. H. B. Irving and Miss Dorothea Baird have promised to give a matinée during their autumn season at the Shaftesbury Theatre in aid of the Mothers' and Babies' Welcome, an institution for helping and feeding nursing mothers in Somers Town St. Pancras.

REPORT OF THE ROYAL COMMISSION ON THE CARE AND CONTROL OF THE FEEBLE-MINDED.

III.[1]

ON the establishment of the Commission in Lunacy in 1845 the number of paid Commissioners was, as it is now, six. At that time visits had to be paid to 25,000 lunatics. On Jan. 1st, 1906, the number of lunatics to be visited had risen to 116,361. Much evidence has come before the Royal Commission indicating, as might have been expected, that it has become impossible for the Commissioners in Lunacy to perform efficiently the duties assigned to them. One of them said: "The Commissioners are satisfied that they can no longer continue to discharge those duties in as complete a manner as they have hitherto endeavoured to discharge them unless they are strengthened by an addition to their number. ...... As it is, their duties have to be discharged so hurriedly as to be good for neither the work nor the workers." So also Dr. G. H. Savage in his evidence said: "I may say the visitation by Commissioners, when they talk of being able to see 800 patients in a day, although a large proportion are weak-minded, must mean very imperfect visitation."

Parallel with, and in some respects overlapping, the jurisdiction of the Commissioners in Lunacy is the authority exercised by the judges of the Supreme Court. The department which has to do with the work of this jurisdiction consists of Masters and Visitors, and its cost formed for the year ending March 31st, 1906, a grand total of £19,805. The number of patients with whom it has to do is 3782. On the other hand, the cost of the Commission in Lunacy for the year 1904–05 was £14,752 and the number of patients visited was 116,361. On the one hand is a jurisdiction of ancient origin, based on the prerogative of the Crown and protecting the few individuals of unsound mind who are possessed of property. On the other hand is the Commission in Lunacy established by statute for the purpose of preventing abuses and protecting the persons of lunatics irrespectively of property qualification. The work of the former body is at least not excessive, while the work of the latter is so excessive that it cannot be efficiently performed. It has therefore appeared to the Royal Commission advisable to consider whether an amalgamation of the two bodies would be expedient. The evidence disclosed a divergence of opinion between the Commission in Lunacy and the judicial authority as represented by the Masters in Lunacy and the Chancery Visitors. The Commissioners in Lunacy were of opinion that an amalgamation was necessary, while the Masters and the Visitors were strenuously of opinion that their isolated position should remain unimpaired. This latter view seems in part founded upon the dissimilarity of the constitution and work of the two bodies and in part upon the likelihood that the Chancery work would be performed less efficiently after the amalgamation and the work of the Commission in Lunacy not appreciably better performed. At present the Masters and Visitors have a considerable amount of work for which there is a sufficiency of workers, while the Commissioners have an excessive amount of work with a striking deficiency in the number of workers. As a result of its deliberations upon this part of the subject the Royal Commission has made certain recommendations for the immediate betterment of the administration. In the first place it is recommended that the Lord Chancellor should, acting under the Lunacy Act of 1890, amalgamate the office, duties, and staff of the Chancery Visitors with the office, duties, and staff of the Commissioners in Lunacy, that under the same Act he should appoint two additional medical Commissioners, and that by the immediate appointment of honorary Commissioners he should fill up the vacancies on the Board of the Commission in Lunacy.

How to provide for chronic and harmless patients otherwise than in asylums is a question to which the Royal Commission has paid considerable attention. Four alternatives presented themselves: 1. To build separate "intermediate" or "workhouse" hospitals, which would be fitted for the reception of senile dements and which might be of cheaper ventrifixation. Among the complications are enumerated marked retraction of the scar; constant hypogastric pain; retraction of the cervix even into the abdominal cavity, the anterior portion of the uterus becoming a thick fleshy mass or tumour obstructing labour, the posterior portion becoming thinned out and even rupturing; atony of the uterus to an extreme degree; malpresentations; besides the regular troubles of pregnancy in the most distressing forms. This is the operation of which Dr. Clarence Webster of Chicago says in his text-book it "may be recommended." His own operation for backward displacement is a method of shortening the round ligaments. He passes them through the broad ligaments, then under the utero-ovarian ligaments, and fixes them to the *posterior* wall of the uterus. What will happen after such an operation when the woman becomes pregnant does not appear to be as yet indicated by any volume of statistics. I have looked through most of the American manuals of gynæcology and it may be stated generally that the authors follow Kelly or do worse. Dr. E. C. Dudley of Chicago, for example, whose work is deservedly held in high esteem in the United States, "uses two formaldehyde catgut sutures, one on each side of the posterior wall of the corpus uteri."

---

[1] Nos. I. and II. were published in THE LANCET of Sept. 19th (p. 890) and 26th (p. 959), 1908, respectively.

Among the books which are read in England for guidance is "Diseases of Women," by Dr. G. E. Herman. If I understand the author's meaning in the paragraph headed "How to Perform Ventral Fixation" I must say, with deep regret, that I regard his method as defective and faulty in almost every detail, even down to the "blunt" volsella. The first suture is made to enter close to the Fallopian tube; the abdominal muscle, not the peritoneum and fascia, is depended upon for adhesion, suspension, and support of the uterus; catgut is the material employed to fix the fundus in the wound and a silk thread is inserted still further back. Silk sutures passing through the skin and uterus are allowed to remain *in situ* for eight days, as if suppuration in the suture tracks was a thing to be aimed at. The patient is kept in bed only a fortnight—too short a time for the production of adhesions which will not be stretched by the weight of the uterus on exertion. The defects of the operation, described by Sutton and Giles, are in the material "fishing gut," which is referred to as if it stood on the same level of suitability with silk for buried sutures, and in the fewness of the sutures. The operation may be completed with one suture through the uterus and peritoneum only! "If desirable two or more sutures may be introduced." In the long run such suturing must inevitably produce a "new ligament," a bowel trap. Exercising such judgment as I am capable of, I cannot see why such operations should be designated ventral fixation, or why they should ever be expected to give more than temporary relief from the symptoms due to retroflexion. That relapse is common I am convinced from cases which I have had opportunities of examining after slipshod operations. The operation which used to be performed by Laroyenne of Lyons complied with all the requirements necessary to confer permanent benefit. Instead of using the volsella above the isthmus to steady and manipulate the uterus, Laroyenne employed a stem in the uterine canal which was managed by an assistant—a detail of the technique possessing obvious disadvantages. I understand that Laroyenne's disciples and followers have improved upon his methods in the direction which experience obviously indicated.

Some of the German operations appear to be worthy of imitation with modifications. Olshausen's method is defective in so far as he has adhered to his original method of fixing in the wound the cornua of the uterus and the Fallopian tube. The method, associated with the names of Leopold and Sippel, appears to be a good operation with the drawback that sutures pass through both the external integument and uterus. Ventrifixation is hardly mentioned by Küstner who writes the chapters on malpositions of the uterus in Veit's "Handbuch der Gynäkologie." Küstner makes much of the "beweglichkeit" of the uterus, but the need for mobility is a pure *a priori* assumption. He cannot find a shred of evidence in support of his objections in the practice of anyone who does an efficient operation by safeguarding the upper half of the corpus uteri. Compare also Döderlein and Krönig, "Abschätzung der verschiedenen Operationsmethoden gegeneinander" in Operative Gynäkologie.

The operation.—In performing the operation of ventrifixation I have discarded all suture material except catgut and the finest silk thread which can be conveniently manipulated. At first I used to try to close completely the vesico-uterine fold but now for several years I have introduced only two sutures, one at each side, well below the lowest point of the abdominal wound. This is quite sufficient practically to close the fold without interfering with the distension of the bladder, and it is therefore a preventive to any possible insinuation of intestine. The next step is to suture the peritoneum near the edge of the wound at each side. The fine silk sutures are introduced from the outside surface of the peritoneum, passed through the peritoneum, and after taking a good hold of the uterus low down and near its margin they are brought back through the peritoneum and firmly tied. The knot is thus always extra-peritoneal. Two or three such sutures are, as a rule, introduced on each side. The same process is now continued with this addition, that the next sutures include the fascia as well as the peritoneum on each side. The transverse sutures are next introduced. These are two or three in number; they consist of fine silk and include fascia and peritoneum at the sides, and each takes a fairly extensive hold of the anterior surface of the uterus. The highest of the sutures is placed less than half-way up from the isthmus to the fundus. In complicated cases, and when the prospect of pregnancy is very remote, the sutures have been placed occasionally a little higher. All the sutures that penetrate to any part of the uterine tissue are buried sutures at the finish. The abdominal wound is closed in the usual way, and it is an advantage to suture separately the edges of the fascia with fine silk. The last step in every case is the introduction of a glycerine pad pessary into the vagina to press forward and support the uterus as a splint during the formation of adhesions. The patients are kept in bed for about a month.

It will be seen that this operation of hysteropexis hypogastria differs in principle as well as in organic details from ventrifixation or ventrisuspension described in many articles and text-books. Among the most important of the differences in its bearing on pregnancy and parturition is the avoidance of thickening of the anterior walls of the uterus. My article on Hypertrophy and Erosion of the Lip of the Os Uteri, a Pathognomonic Sign of Chronic Flexion,[3] appears to me to have produced irrefragable proof by the logical method of concomitant variations that in chronic retroflexion the nutrition of the uterine walls varies with the relations of body to cervix, and in retroflexion there is always thickening of the posterior or concave wall of the uterus, the visible sign being hypertrophy with erosion of the posterior lip of the os uteri. If the uterus is brought into anteflexion to a pathological extent such thickening of the anterior wall and thinning of the posterior wall as to cause dystocia must be the result; if pregnancy occurs this thickening may even develop to the extent of requiring treatment by embryotomy or Cæsarean section. All ventrifixation operations in which sutures are introduced into the fundus uteri or farther back, and especially vagino-fixation operations, produce this pathological thickening of the anterior uterine wall and dangerous thinning of the posterior wall. Some very dreadful cases of complications resulting from this malposition have been reported from America and Germany. There are fewer from France, because of the prevalence of a better technique. On this subject, writing in the *L'Echo Médical du Nord* in 1904, Oui has been friendly enough to state: "The fixation of the fundus by Leopold, Mundé, and Noble, especially when it is fixed near the symphysis, is particularly objectionable. The only proper place for the insertion of the sutures is the anterior wall of the uterus below the line of insertion of the tubes. The methods of Sinclair and Laroyenne for this reason are preferable to those described by other authors." The aim of the operator should be to retain the uterus in a position the most nearly attainable to the normal anteversion without any undue dragging or tension at any point. If this rule is not observed the tissues of the uterus will resent the unnatural relationship, and if pregnancy occurs the most favourable result will be dystocia, the least favourable an obstetric disaster.

Another difference in favour of hysteropexis hypogastria is that it may justly claim to be an effective method for the cure of sterility. Pregnancy after operation instead of

THE LANCET.

LONDON: SATURDAY, OCTOBER 3, 1908.

There is No Decay.

WE have before us a reprint of a lecture with this title delivered under the auspices of the Independent Lecture Society of Liverpool in the early part of this year and now published[1] at a popular price. We commend its perusal to medical men because the rapid evolution that is taking place in our science makes due appraisement both of our workers and our theorists very difficult, and the lecturer has many shrewd and humorous things to say upon this situation. Not infrequently we read indiscriminate praise of the heroes of to-day, while in other quarters we may find that it is the old masters who are especially praised, and unfortunately this is easiest done by belittling the period in which we live. It is especially against this latter form of criticism that the lecture is delivered, and the tendency to decry the great men of to-day is found in our profession perhaps as much as in other callings. The habit of detracting from contemporary performances, indeed, is not an uncommon one. It is not confined to those whose duty or pleasure it is to publish their views upon literature, art, science, philosophy, or religion, but it prompts the utterance in private circles of opinions held by persons who are scrupulous in other matters to accord to every man his due, and who would be keenly distressed to realise that they were denying justice in their ill-considered judgments. It is chiefly, according to our experience, in conversation that medical men appear to hold their leaders of to-day cheaply; public references to them in literature are usually much more generous. In the words of Mr. ROSS, "An overweening modesty in us seems to persuade us that it is quite impossible we should be fortunate enough to be the contemporaries of great men," and he attacks this particular phase of pessimism by showing that it has been manifested in all ages and countries, and against many to whom the mature judgment of succeeding generations has accorded undying fame. The very persons who are used to bring the modern celebrity into his right and modest place, in their turn, when they were modern, were subjected to analogous treatment. A lecturer in discussing this situation would naturally find his most striking instances of misleading criticism in opinions upon literature and art, which though delivered by the pundits of their day have since been proved absurd, but Mr. ROSS's words, as he himself perceived, also have their meaning for a scientific audience.

In literature and in art the need for special training, for knowledge, and for judicial qualities on the part of the critic is not recognised by the general public, and criticism is often accepted as sound and as evincing special discernment and acumen, merely because it voices the uneducated opinion of the average individual. The same does not quite hold good in science. The average individual himself, because he can see a picture so far as his eyes are concerned, and can read a romance or a poem so far as education in reading is concerned, believes himself qualified to pronounce upon it, and if he does not praise or condemn it in the public press or on the public platform he has no hesitation in according his meed of approval or disapproval to the utterances of those who do. The public press, in such matters at all events, is tempted by the line of least resistance, and the critic not too learned and not of too original a bent of mind is likely to find a smoother path before him than he who preaches to a limited but discerning audience in the wilderness. In science and in philosophy it is somewhat different, for so far as public or lay opinion is concerned the smatterer who cannot go to original sources and study for himself at first hand has to take his opinions from reviewers or critics who, in order to lay what is wanted before a special audience, must be themselves well trained. All great men of science have not, of course, experienced the pleasure of seeing their discoveries appreciated by their contemporaries, but the judgments, whether favourable or the reverse, have generally come from competent persons. In these circumstances Mr. ROSS finds examples of the want of appreciation accorded to art and literature by contemporary critics more frequent and more obvious than any similar mistakes made with regard to scientific performance. He instances the records of contemporary opinion denouncing the drama of EURIPEDES; he lays before us the opinion of GRAY that England made no advances in painting and sculpture, so that the poet wrote of these arts to a correspondent in 1763: "You are generous enough to wish, and sanguine enough to see, that art shall one day flourish in England! I, too, much wish but can hardly extend my hopes so far"; and he calls to our minds the reception accorded to such men as WORDSWORTH, COLERIDGE, BYRON, KEATS, SHELLEY, SWINBURNE, and ROSSETTI. He also emphasises the point in the passages which give the title to his lecture that even in periods in which posterity claims to find decay in a particular branch of intellectual development there has been no decay of intellect but a progressive development of it in fresh directions, due possibly to causes connected with the progress of public events, or perhaps to reasons less easily traced and assigned.

Admitting that the scope of his discourse is, strictly speaking, limited to literature and art, and disclaiming the right to speak with authority of science, Mr. ROSS here uses the progress of medicine in happy illustration of his theme. "Let us take medicine," he says. "Medicine is primarily based upon the study of anatomy or structure, of physiology, or the scheme of structure carried out in life, and of botany and chemistry as representing the vegetable and mineral worlds where the remedies are sought. Anatomy soon reaches a finite position when a sufficient number of careful dissections have been made; the other divisions used confinements and she had post-partum hæmorrhage every time. It was on account of flooding after the seventh labour that Dr. Fraser was first called in by a midwife in attendance. At the time the patient was seen by me in consultation with Dr. Fraser the cervix was found to be so badly lacerated that it simulated malignant disease. The uterus was acutely flexed backwards. Ventrifixation was considered to be the best treatment. Patient at interview (June, 1908) said that her three confinements since the operation have been much "better." No hæmorrhage after labour. No discomf[illegible] The uterus was found to be in normal position; [illegible] backward displacement. (This is Case 2 in [illegible] "Hypertrophy and Erosion ...... a Pathognomonic Sign" already referred to.)

[1] There is No Decay a lecture delivered by Robert Ross in the Old Bluecoat School, Liverpool, on Feb. 12th, 1903. Liverpool, The Northern Publishing Company, Limited. Pp. 38. Price 1s.

CASE 7.—Mrs. W. L., aged 27 years; not been pregnant. Patient of Dr. A. Carmichael, Barrow-in-Furness. Retroflexion with symptoms; dysmenorrhœa worse since marriage. Examined under anæsthesia on May 11th, 1905. Uterus in acute retroflexion; body so large that it could not be manipulated forward without violence; not fixed by adhesion. *Hysteropexis on May 15th, 1905.* No divergence from the routine. Post-operative history without incident. Patient went home on June 21st. When pregnancy occurred in 1906 there were none of the usual symptoms, except amenorrhœa, and it was *only the increasing* volume of the uterus that settled the diagnosis. Labour began on Oct. 17th, 1906. It was rather slow at first and under anæsthesia occipito-posterior position was made out and rectified by manipulation. Forceps were then applied and labour completed without any incident worth noting. The puerperium was absolutely normal. The child was kept at the breast for some months, then the milk became scanty without apparent cause, except the maternal constitution.

These illustrative cases might be multiplied at intolerable length, but the present purpose can be served by the select few. The cases here given illustrate some of the chief points in the clinical history of pregnancy after hysteropexis. They are not chosen as the most favourable, but as characteristic some of them with even slightly unfavourable features.

The operation could not be pushed even though any one was foolish enough to try; it must be judged on its merits fairly stated, and proved by experience. I believe it will stand the test.

Manchester.

CANCER OF THE COLON: A STUDY OF 72 CASES.

BY H. S. CLOGG, M.S. LOND., F.R.C.S. ENG.,
ASSISTANT SURGEON TO CHARING CROSS HOSPITAL; SENIOR SURGEON TO THE EVELINA HOSPITAL FOR SICK CHILDREN, LONDON.

THE portion of bowel under consideration is that which reaches from the ileo-cæcal valve to the termination of the pelvic colon, that is about the level of the third piece of the sacrum. Cancer may occur anywhere in the colon, but it has a special selection for certain sites. It is convenient for the purposes of classification and treatment of cancer of the colon to divide the latter into its several arterial segments, by which I mean that the colon may be more or less divided into several portions by the vessels which supply it. Commencing at the cæcum these vessels are—the ileo-colic, the right colic, the middle colic, and the inferior mesenteric arteries. The ileo-colic and right colic arteries supply the cæcum and greater part of the ascending colon. It is better to consider this tract of bowel as one for the present purpose. The middle colic by its two main branches supplies the transverse colon and the termination of the ascending and commencement of the descending colons. The inferior mesenteric artery supplies the remainder. In this series of 72 cases the growths were distributed as follows:—

1. *Those in connexion with the ileo-colic and right colic arteries.*—17 were in this region. This site is conveniently called the cæcal region. The actual anatomical position of the growth is variable. In 16 of the cases the growth was examined either post mortem or as removed at operation. In only two was the cæcum entirely free from growth. The growth in these was in the ascending colon a little way above the site of the ileo-cæcal valve. In the remaining cases the cæcum was in whole or in part involved, often together with the ascending colon. Although all growths here are not strictly limited to the cæcum (on the contrary, a growth in the ascending colon may not invade the cæcum at all) I consider it better to include them under one heading since I believe that the lymphatic drain is very much the same, and hence from an operative point of view they are inseparable, and I think clinically they will generally not be distinguishable.

2. *Those in connexion with the middle colic artery.*—There were 18 in all situated in the bowel supplied by this artery. They were distributed as follows: (*a*) at the *hepatic flexure* there were five. These were more or less accurately at the flexure, but involved the colon on either side of the flexure also to some extent. (*b*) In the *transverse colon* without involvement of either flexure there were three. (*c*) In the region of the *splenic flexure* there were ten. The growth was not always strictly at the flexure, for in two cases it was at the commencement of the descending colon about two inches or so below the flexure. Such growths are in whole or in great part supplied by the middle colic artery and hence are included here.

3. *Those in connexion with the inferior mesenteric artery.*—There were 37 situated in the iliac and pelvic colons. The distinction of this part of the bowel into the *iliac* and *pelvic* colons is in accordance with anatomical description and founded upon the more common arrangement of the peritoneum. But the latter is very uncertain and for the present purpose it has no particular bearing and the bowel is best considered as one and called the *pelvic* colon. The only feature of importance which can be assigned to the division is that a growth occurring in the bowel which is fixed to the iliac fascia is more likely itself to become adherent than one in the bowel which is suspended by a mesentery.

The importance of determining which arterial segment bears the cancer is, I think, very prominently brought out in the study of the lymphatic drain of various parts of the colon. It seems to me of great importance to bear this in mind when operating for these growths. Any operation for cancer is not merely that of removal of the primary growth but also its lymphatic drain as thoroughly as can be performed in accordance with the anatomy of the part.

In the results which I am about to report it may be understood that all cases which were examined post mortem or specimens which were removed at operation were submitted to microscopic examination. Several sections of each gland were examined, but not serial sections.

Cancer of the Colon in many Cases a Local Disease.

Forty-one cases I have traced to the post-mortem room The duration of symptoms in these ranged from a week to three years. In only six were there any visceral deposits, that is, in just under 15 per cent. It may be pointed out that it was not in those which suffered from a long duration of symptoms that the visceral deposits occurred; on the contrary, however, for the duration of symptoms was comparatively short, varying from two to six months. In 20 further cases I have been able to trace the after history. Some of these were successful excisions, others were those upon whom colostomy had been performed. The latter were not microscoped, and hence the diagnosis must remain in doubt. But it is probable that most, if not all, were cancer, seeing that there are not many conditions which may be confused with cancer of the large intestine. Many of these cases I have seen personally; in others I am indebted to the medical practitioner in attendance for very kindly furnishing me with the notes. In only one was there evidence of secondary visceral deposit. In one other upon which an anastomosis had been performed the whole abdomen filled with growth before death, and it was impossible to say where it was. These clinical observations are obviously unsatisfactory, but they may at the least be regarde as suggestive and bearing out the post-mortem pathology. In the cases in which there were secondary visceral deposits post mortem the liver was involved in every one. In two in addition the ovaries were involved, in one case both ovaries, and in the second only one. In neither of these two was there any peritoneal deposit. Cancer of the ovary secondary to bowel cancer is well recognised and there are several papers upon the subject in the literature. The primary growth was in one at the commencement of the descending colon and in the other in the pelvic colon. In a further case the peritoneum was diffusely studded with tiny secondary growths, in addition to the infection of the liver. It may be gathered from these figures that cancer of the colon is in many cases a local disease and that secondary visceral deposits are not the great barrier to any radical operation.

The Lymphatic Spread.

In a communication to the *Practitioner* in 1903 I published some observations on cancer of the colon with especial reference to its lymphatic spread. Since that date I have had opportunities of extending those observations upon many more cases working on the same lines. The lymphatic drain come from a class of persons who lead reckless, intemperate, and poverty-stricken lives. Contrary to the general opinion, the Commissioners believe that prison life as it exists in Ireland does not in any way promote the development of tuberculous disease. That life consists of open-air employment, good and sufficient food, perfect cleanliness, and general hygienic conditions by night as well as by day, together with properly regulated association at labour and during exercise. The majority of prisoners are occupied for the greater part of the day in manual labour in the open air. Two of the chief employments—stone-breaking and firewood making—are entirely open-air work, and a considerable area of land is attached to most of the Irish prisons, on which many of the prisoners are employed in gardening. The classes working in association at bag-making and mat-making have the advantage either of constant open-air life or of well-ventilated workshops. The prison cells are in all cases well ventilated and well lighted, and are kept thoroughly clean. Smoking is allowed to a portion only of the prisoners, and to these only during the hours of exercise, so that there is less temptation to spit than in outside life—one dangerous source of infection is thus removed. The medical officers exercise great care in the treatment of individual prisoners, and they are authorised to prescribe for prisoners in cells, as well as for patients in hospital, such alterations in diet and exercise as to them seem necessary on medical grounds. To most of the prisoners this change in the conditions of life is definitely beneficial. As drinking to excess is the cause of most of the minor offences in Ireland, it will readily be understood that many of the prisoners on committal present the appearance of having been ill-fed as well as ill-clad, and of having been exposed to cold and wet and to the hardships of a badly regulated life. Many of them also are obviously the victims of intemperance. For such the shelter of prison, with its wholesome food, equable temperature, and healthy occupation, constitutes a veritable sanatorium. It is mentioned in the report that fresh milk enters largely into the composition of prison dietary, each prisoner consuming on the average a pint daily. In these circumstances, we are not surprised to learn that under the *régime* provided for them the prisoners of Ireland are improved in every way and that on their discharge they weigh more than on their committal to prison. Very complete statistics of disease and mortality among Irish prisoners are contained in the report and from these we gather that they enjoy remarkably good health. It appears to us that these institutions, under the admirable management of the Prisons Board, will prove a valuable asset in the crusade against tuberculosis now going on in Ireland.

◆

Syphilis in Uganda.

WE have received from Colonel F. J. LAMBKIN, of the Royal Army Medical Corps, under the title of "Syphilis in the Uganda Protectorate," a paper read by him before the United Services Medical Society, and containing the most ghastly account of the ravages of the disease which has appeared since the first publication of the history of the siege of Naples in the fifteenth century. Notwithstanding the terrible consequences of sleeping sickness in the Protectorate Colonel LAMBKIN is inclined to regard syphilis as a still greater evil, possibly because the trypanosome kills its victims, while the spirochæta of syphilis leaves them to transmit the consequences of their malady to future generations, and thus to lay the foundations of racial degeneracy or extinction. He tells us that while the opening up of Africa from the west has been responsible for the introduction of sleeping sickness, the opening up from the east has been the main cause of the visitation of syphilis. It is not that the disease was previously unknown, for there is evidence of its occasional presence for many years, and it is supposed to have been introduced originally about 1850, during the Arab invasion, but it existed only to a small extent. About 12 years ago there was a more or less sudden outbreak among the Baganda tribe who are the predominating inhabitants and who are described as of mixed negro type, sturdy in physique, extraordinarily intelligent, willing, hard-working, and on the whole honest. Colonel LAMBKIN quotes from Sir HARRY JOHNSTON a description of them as "the Japanese of the dark continent, the most naturally civilised, charming, kind, tactful, and courteous of black people." Since the introduction of syphilis among them it has gone on increasing, both numerically and in virulence, *until* at the present time more than half the population of the Protectorate is infected. In some districts it is estimated that 90 per cent. suffer; the *infant mortality which it* produces is as high as 50 or 60 per cent., *and it is the chief* cause of the sterility which exists throughout the country. As things are at present, the entire population is in danger of being exterminated by syphilis in a very few years, or of being left a degenerate race fit for nothing To complete the picture of the magnitude of the evil we are told that the Protectorate has an area of 130,000 square miles, and a population of 3,000,000, while the population of Uganda proper is about 1,000,000, of whom 100,000 are said to be Christians.

Colonel LAMBKIN describes the type of the disease as being that which is usual when it is implanted on virgin soil and allowed to run riot without treatment. It resembles the late Sir WILLIAM FERGUSSON's description of what he saw in like circumstances in Portugal in 1813—namely, mutilation everywhere. He said then of *Lisbon* that more cases of mutilation from syphilis could be seen in that city in one day than could be found anywhere else in a year. Under analogous conditions the disease has assumed its well-known characteristic virulence. In the primary form the true Hunterian chancre is the rule, and *this often takes* on a phagedænic character and produces wide destruction of surrounding parts. The second stage is characterised by intense and confluent eruptions, ulcerations of the mucous membranes, laryngitis, iritis, periostitis, affections of the joints, profound anæmia, cachexia, and general disturbances of nutrition. In some cases the principal secondary manifestations are of a nervous kind, as exemplified by neuralgic pains, asthenia, paralysis, and analgesia. The tertiary stage is represented by early rupial syphilides which extend rapidly and deeply over the body and limbs; osteo-arthritic manifestations, with s

The splenic flexure region.—There were ten cases of cancer here. The growth was practically at the flexure in eight and in two was really at the commencement of the descending colon. Seven were examined post mortem, but in only six have I a note of the glands. In one the growth was of large proportions and adherent to neighbouring structures and no glands could be found. In the five cases glands were enlarged in the vicinity of the primary growth, in the angle of the flexure or a little posterior to it in relation to the spleen, or to the inner side of the descending colon. In one case glands were found in the adjacent great omentum. In three glands were also present in the mesocolon near to the lower border of the proximal transverse colon. In a further case which was successfully excised the patient is well six years after. In this there was a chain of glands running along the transverse colon and half of the latter was removed. In four out of the six cases the glands were infected with cancer. Glands *per se* would not have prevented a radical operation in any one of these cases.

I would suggest that the removal of a growth in the splenic flexure region be planned on the same lines as that for one of the hepatic flexure. The splenic flexure may be mobilised by division of the peritoneum on the outer side of the descending colon and the costo-colic ligament. I would also suggest that the corresponding half of the transverse colon also requires removal in order to remove the lymphatic drain which is in the mesocolon. I have not seen glands in association with the left colic artery but it seems probable that the lymphatics may pass this way. The descending colon, after division of the peritoneum on its outer border, may be stripped inwards over the lower pole of the kidney and freely excised with the possible lymphatic drain along the left colic vessels.

The Lymphatic Drain of the Ilio-pelvic Colon.

The inferior mesenteric artery supplies this tract of bowel. Arising from the inferior mesenteric artery at about half to three-quarters of an inch from its commencement is the left colic artery. The latter runs upwards and to the left well over the iliac crest to the descending colon, anastomosing with the middle colic artery below the splenic flexure. The left colic artery may be said to supply that part of the colon from two inches or more below the splenic flexure to a point in the iliac fossa. The anastomosis between the left colic and the next vessel (the sigmoid artery) is a little below the level of the iliac crest. The sigmoid artery arises from the inferior mesenteric artery just below the left colic. It usually almost at once divides into two branches of nearly equal size. These vessels form arches which supply the loop of bowel from somewhere near the iliac crest to the lower end of the pelvic colon—that is, to about three inches or so above the peritoneal reflection at the base of the pelvis. The sigmoid vessels are for the most part between the layers of the mesentery of the pelvic colon but if the latter be absent in the iliac fossa for a short course the upper arteries may be retroperitoneal. The third vessel from the inferior mesenteric is the superior hæmorrhoidal artery. This passes over the pelvis in close contact with the brim and supplies the lower part of the pelvic colon.

Assuming that the glandular drain from the pelvic colon would more or less closely follow these vessels the first care is to determine from which arterial segment of bowel the cancer arises. This has been possible in many cases without any dissection. But in those cases where the mesentery is short the point may further be demonstrated after freeing the bowel by division of the peritoneum in the iliac fossa on its outer side and stripping it in towards the mid-line. The bowel is thus separated from the iliac fossa with the retroperitoneal tissue over the ureter and spermatic vessels to the origin of the inferior mesenteric trunk. By prolonging the incision in the peritoneum down along the pelvic wall, taking care to avoid the above-named structures, which have been already exposed and can therefore be readily protected, the whole ilio-pelvic colon may be separated from all its connexions, except the vascular supply and the leaf of peritoneum on the mid-line aspect. This enables the arteries to be freely exposed and it may be determined which vessel supplies the cancer-bearing portion of bowel.

Eighteen post-mortem examinations were made upon growths in the pelvic colon. In 16 of these the growth was in that part of the colon supplied by the sigmoid artery. In two it was quite low down and was supplied, anyhow in part, by the superior hæmorrhoidal artery. In no case was a growth situated in that part of the colon from two inches or so below the splenic flexure to the middle (about) of the iliac fossa. In some (two at least) of the growths in the splenic flexure region the left colic artery in part supplied it, or presumably it did as judged from its situation. I have not found any glands along this artery but then my chances have been too few to observe growths in this region, but nevertheless should consider that in such growths it would be advisable to remove the descending colon, the peritoneum, retroperitoneal tissues, and left colic artery. In 17 of the 18 cases enlarged glands were present. In every instance they were found in close proximity to the primary growth. In six glands were found at some distance from the primary growth near to, or at the base of, the mesentery. They were more or less in association with the vessels supplying the bowel. If the bowel were well freed as described above it was seen that the glands were not the retroperitoneal ones along the iliac vessels, but were actually situated between the layers of the mesentery. The extent of the glandular enlargement varied in these six cases, but in three it may be said that the highest gland was well below the origin of the sigmoid artery, whilst in three glands were higher than this and were more or less in connexion with the inferior mesenteric artery, and even higher than this, that is, they were the lumbar chain. Believing that the spread would tend to be finally along the inferior mesenteric artery I have always looked particularly for glands along the latter vessel, but have only found them in the cases indicated. In many cancer was absent in the glands, and, in fact, in only two-thirds of cases were cancer cells found. In addition to these post-mortem examinations there were eight cases of excision, with a very moderate resection of mesentery. In one a local and superficial glandular recurrence took place; this was excised and four years later there was no evidence of recurrence. A second recurred extensively in the lumbar glands. Five of the remaining six are in good health at intervals varying from ten months to three years. The sixth cannot be traced.

These figures incline one to the belief that cancer in this region is, for some time anyhow, a more or less local disease and involves those glands only in the immediate neighbourhood. It also shows that all enlarged glands are not necessarily cancerous, and it may be suggested that if the radical operation is thought impossible on account of glandular involvement only the operation need not be always at once renounced, but may be undertaken in the hopes that the level of an extensive resection will be above the most distal glandular cancer-infection. It may be mentioned here that in this series glandular involvement only was not in any single instance a barrier to the radical operation. In three cases, it is true, glandular infection would have, I think, prevented removal, but in these there were other contra-indications, such as adhesion of the primary growth.

Although a very fair amount of success has in this series been attained by the removal of a very moderate amount of the lymphatic tract it is not my intention to advocate such a limited resection. My observations lead me to the belief that in cases where the cancer is in that part of the bowel supplied by the sigmoid artery a resection of this loop with the contained mesentery to the origin of the vessel will be the most satisfactory method of dealing with it. It is quite easy to ligature the inferior mesenteric trunk nearly at its origin with the removal of the tissue around it, but in the cases I have examined with glands along this vessel this would not have been sufficient. It has always seemed to me that such a procedure would of necessity mean a colostomy, and having very serious doubts whether anything is gained by it I think that a resection just below this and the avoidance of a colostomy would in the majority of cases be equally efficient.

The operation in brief is as follows. A long left paramedian incision gives the best access. The peritoneum is then divided in the iliac fossa to the outer side of the colon; this division may extend up some distance along the descending colon if necessary, and may be prolonged downwards into the pelvis. The colon and the retroperitoneal tissues are stripped up from the iliac fossa over the ureter and spermatic vessels which are seen and guarded, and it is necessary to expose these before the incision is carried down into the pelvis. This freeing of the colon may be carried come from a class of persons who lead reckless, intemperate, and poverty-stricken lives. Contrary to the general opinion, the Commissioners believe that prison life as it exists in Ireland does not in any way promote the development of tuberculous disease. That life consists of open-air employment, good and sufficient food, perfect cleanliness, and general hygienic conditions by night as well as by day, together with properly regulated association at labour and during exercise. The majority of prisoners are occupied for the greater part of the day in manual labour in the open air. Two of the chief employments—stone-breaking and firewood making—are entirely open-air work, and a considerable area of land is attached to most of the Irish prisons, on which many of the prisoners are employed in gardening. The classes working in association at bag-making and mat-making have the advantage either of constant open-air life or of well-ventilated workshops. The prison cells are in all cases well ventilated and well lighted, and are kept thoroughly clean. Smoking is allowed to a portion only of the prisoners, and to these only during the hours of exercise, so that there is less temptation to spit than in outside life—one dangerous source of infection is thus removed. The medical officers exercise great care in the treatment of individual prisoners, and they are authorised to prescribe for prisoners in cells, as well as for patients in hospital, such alterations in diet and exercise as to them seem necessary on medical grounds. To most of the prisoners this change in the conditions of life is definitely beneficial. As drinking to excess is the cause of most of the minor offences in Ireland, it will readily be understood that many of the prisoners on committal present the appearance of having been ill-fed as well as ill-clad, and of having been exposed to cold and wet and to the hardships of a badly regulated life. Many of them also are obviously the victims of intemperance. For such the shelter of prison, with its wholesome food, equable temperature, and healthy occupation, constitutes a veritable sanatorium. It is mentioned in the report that fresh milk enters largely into the composition of prison dietary, each prisoner consuming on the average a pint daily. In these circumstances, we are not surprised to learn that under the *régime* provided for them the prisoners of Ireland are improved in every way and that on their discharge they weigh more than on their committal to prison. Very complete statistics of disease and mortality among Irish prisoners are contained in the report and from these we gather that they enjoy remarkably good health. It appears to us that these institutions, under the admirable management of the Prisons Board, will prove a valuable asset in the crusade against tuberculosis now going on in Ireland.

◆

Syphilis in Uganda.

WE have received from Colonel F. J. LAMBKIN, of the Royal Army Medical Corps, under the title of "Syphilis in the Uganda Protectorate," a paper read by him before the United Services Medical Society, and containing the most ghastly account of the ravages of the disease which has appeared since the first publication of the history of the siege of Naples in the fifteenth century. Notwithstanding the terrible consequences of sleeping sickness in the Protectorate Colonel LAMBKIN is inclined to regard syphilis as a still greater evil, possibly because the trypanosome kills its victims, while the spirochæta of syphilis leaves them to transmit the consequences of their malady to future generations, and thus to lay the foundations of racial degeneracy or extinction. He tells us that while the opening up of Africa from the west has been responsible for the introduction of sleeping sickness, the opening up from the east has been the main cause of the visitation of syphilis. It is not that the disease was previously unknown, for there is evidence of its occasional presence for many years, and it is supposed to have been introduced originally about 1850, during the Arab invasion, but it existed only to a small extent. About 12 years ago there was a more or less sudden outbreak among the Baganda tribe who are the predominating inhabitants and who are described as of mixed negro type, sturdy in physique, extraordinarily intelligent, willing, hard-working, and on the whole honest. Colonel LAMBKIN quotes from Sir HARRY JOHNSTON a description of them as "the Japanese of the dark continent, the most naturally civilised, charming, kind, tactful, and courteous of black people." Since the introduction of syphilis among them it has gone on increasing, both numerically and in virulence, until at the present time more than half the population of the Protectorate is infected. In some districts it is estimated that 90 per cent. suffer; the infant mortality which it produces is as high as 50 or 60 per cent., and it is the chief cause of the sterility which exists throughout the country. As things are at present, the entire population is in danger of being exterminated by syphilis in a very few years, or of being left a degenerate race fit for nothing To complete the picture of the magnitude of the evil we are told that the Protectorate has an area of 130,000 square miles, and a population of 3,000,000, while the population of Uganda proper is about 1,000,000, of whom 100,000 are said to be Christians.

Colonel LAMBKIN describes the type of the disease as being that which is usual when it is implanted on virgin soil and allowed to run riot without treatment. It resembles the late Sir WILLIAM FERGUSSON'S description of what he saw in like circumstances in Portugal in 1813—namely, mutilation everywhere. He said then of Lisbon that more cases of mutilation from syphilis could be seen in that city in one day than could be found anywhere else in a year. Under analogous conditions the disease has assumed its well-known characteristic virulence. In the primary form the true Hunterian chancre is the rule, and this often takes on a phagedænic character and produces wide destruction of surrounding parts. The second stage is characterised by intense and confluent eruptions, ulcerations of the mucous membranes, laryngitis, iritis, periostitis, affections of the joints, profound anæmia, cachexia, and general disturbances of nutrition. In some cases the principal secondary manifestations are of a nervous kind, as exemplified by neuralgic pains, asthenia, paralysis, and analgesia. The tertiary stage is represented by early rupial syphilides which extend rapidly and deeply over the body and limbs; osteo-arthritic manifestations, with severe of the alimentary canal. I have been particularly careful in my inquiries to ascertain the previous history, and in no case have I been able to suspect the sequence of simple inflammation and cancer in the intestine.

At the time when the patients came under observation it was only possible to excise the growth in five cases. Suppuration, adhesions to the posterior abdominal wall, to the anterior abdominal wall in one case and the small intestine were the reasons why extirpation could not be performed. I have traced two cases of excision. One was operated upon six years ago and is now in good health. In this the whole cæcum, ascending colon, and a part of the transverse colon with the lower ileum were removed. The second case, a less extensive resection of the colon, is well two years after.

Three cases of anastomosis I have been able to trace. Two died in five and seven months respectively. The third is alive but very weak nine months after the operation.

The clinical characters of growths elsewhere than in the cæcal region.—*Age incidence.*—The youngest was 15 and the oldest 89 years of age. Arranged in decades the numbers were as follows:—

Under 20 years				1 case.	
Between 30 and 40 years				5 cases.	
,,	40	,,	50 ,,	10	,,
,,	50	,,	60 ,,	17	,,
,,	60	,,	70 ,,	15	,,
,,	70	,,	80 ,,	6	,,
Over 80 (89) years				1 case.	

The sexes were about equally affected. There were 29 male and 26 female cases.

Of the 55 cases, I have been able to learn the previous history of 46. In eight of them there was a history of long-continued constipation. In three this had been present practically the whole lifetime. In the remainder it had been present for some years. But constipation was the only feature in these. It was never associated with any pain, diarrhœa, or hæmorrhage, neither was there any symptom elicited suggestive of a simple stricture. In other words, I have not traced in any case the relationship between malignant disease and simple inflammation of the bowel.

The onset of symptoms could practically in all cases be dated with precision. It invariably affected persons in otherwise good health with the exception of those who suffered from chronic constipation, and this was not regarded as anything other than normal by these patients. In a few cases the onset was not quite so definitely fixed. The patients described their symptoms as of a few weeks' or months' duration. But in by far the majority of cases the onset was more or less abrupt and its time of occurrence could be fixed with great precision. The symptoms of cancer are, of course, those which are directly dependent upon a progressive narrowing of the lumen of the bowel and the consequent hypertrophy of the gut above. Recurrent spasms of pain, gurgling of flatus as it is forced through the stricture, the discomfort caused by the inhibition of free passage of intestinal contents, anorexia, gradual failure of health and weight, and a progressive difficulty in the evacuation of the bowels are the main features. The hypertrophied gut above the stricture may be felt, or might be brought into prominence by a little gentle rubbing of the abdominal wall. This ought to be an early sign of a progressive stricture. Such symptoms were in general present in this series. They are all familiar and require no special comment. There are other clinical characters of which brief mention may be made. These are (1) the characters of the motions, and (2) the presence of an abdominal tumour.

1. There is constipation in the majority from the very commencement of the illness. But in a few this has not been so. In this series in about one-ninth this was said not to be present until some time after other symptoms. But in all it sooner or later was present. It may be that the bowels do not move daily or every other day, but what is of equal importance is that the quantity of fæces passed is distinctly less than normal. Attacks of diarrhœa sometimes occurred. Such were noted in about one-sixth of cases only, and in these the growth was in the pelvic colon with one exception, where it was at the splenic flexure. These attacks generally occur after a period of more than usually obstinate constipation. Some catarrh is no doubt set up by the retained and irritating intestinal contents. When the stricture relaxes and allows of a passage once more these catarrhal products are hurriedly rushed along and the result is that several loose motions may be passed for a day or so. Such motions may contain mucus and even blood. This was not a common symptom in this series. It is what is generally referred to as alternating constipation and diarrhœa. Constipation was the characteristic and diarrhœa the exception. When such spurious diarrhœa occurred it was unusual to have more than two or three attacks, and it would be very misleading to give as a symptom of cancer of the colon alternating constipation and diarrhœa. Apart from this diarrhœa mucus was observed in the motions on five occasions. Four of these were growths in the pelvic colon and in one the growth was at the splenic flexure. Blood in the motions was absent in the majority of cases. By this is understood visible blood; in no case was a microscopical or chemical examination made to determine its presence or absence. In one in the transverse colon, two at the splenic flexure, and in only 14 out of 37 growths in the pelvic colon was blood noted. In all it was particularly asked for and the stools were examined whenever possible.

2. *A palpable tumour.*—A tumour was by no means always felt. Its presence will depend upon its situation, its size, and the state of distension of the abdomen. When the abdomen was not too distended to permit of examination a tumour was felt in this series as follows. In two cases out of three at the hepatic flexure, every case (three) at the transverse colon, in three cases out of seven at the splenic flexure, and in seven cases out of 22 in the pelvic colon. In two additional growths in the latter region a mass of undetermined connexions was felt through the vagina. A tumour was palpable therefore in 15 cases out 35 in which the condition of the abdomen permitted of examination—that is, in about 43 per cent. of cases.

The duration of the symptoms of incomplete intestinal obstruction varied considerably before becoming complete. In one the earliest symptom was acute obstruction. No previous history of intestinal trouble could be elicited in this case. The patient was first seen when obstruction had been present for three days and the abdomen was generally distended without evidence of the site of obstruction. That the obstruction was chronic was easily seen from the hypertrophy of bowel. Compensation had been so well maintained that previous to the sudden obstruction there had been no trouble whatever. In two further cases the onset was ten and 12 days previously with an attack of subacute obstruction which yielded to simple measures. Obstinate constipation was present during the succeeding few days which culminated in complete obstruction. Obvious bowel hypertrophy of some duration was present in these cases. The duration of symptoms in the others was from two months to three years. About one-third during this period had suffered from one or more attacks of threatened obstruction which had yielded to aperients or enemata. It may be mentioned that in many (about two-fifths) the administration of frequent and strong aperients had probably actually produced the final obstruction. This may be considered as a warning.

In considering the causes of the terminal obstruction it may be said that there was not one case of volvulus of the bowel above nor one of intussusception, both of which are given as occurring sometimes. In one case the obstruction seemed to be enhanced by the kinking and adhesion of a lengthy loop of bowel above the growth. In two others it was probable that an abscess around the growth determined in part the obstruction. In no case could the impaction of a foreign body or fæcal accumulation be said to be the cause of obstruction.

The onset and progress of the terminal obstruction varied somewhat. In three acute dilatation of the cæcum was the earliest sign. So sudden was this and so pronounced was the distended cæcum that a volvulus or some other mechanical acute obstruction might have been suspected. All three cases gave a comparatively short history. In three in which the symptoms had been by no means urgent but merely those of chronic obstruction an acute dilatation of the colon occurred. The abdomen rapidly became swollen, vomiting was profuse and foul-smelling, and collapse was decidedly marked. Compensation in these had been maintained up to a certain point and then it would appear that the colon suddenly gave out. Possibly antiperistalsis may explain the cases of acute dilatation of the cæcum. In the majority the obstruction was more slowly progressive. The abdomen more slowly distended due to the more or less gradual distension

£200 per annum. Such an inordinate amount of attendance—day and night—was called for that they found it impossible to give it. They have now refused to continue the arrangement, offering, however, to attend all who cannot afford to pay anything for a fixed stipend of £50 per annum, other people to be charged according to their financial position from 6*d.* to 5*s.* an ordinary visit and more for night visits. It is very doubtful if these by no means exorbitant terms will commend themselves to the good people of Bellinzona after they have been accustomed to knock up a medical man at all hours of the day and night without any thought of extra expense to themselves.

A THEORY AND A CRITICISM.

WE publish on p. 1051 a letter from Mr. G. Sherman Bigg which purports to be a criticism of the views generally current of the causal relation of bacteria to disease and offers as a theory the view that bacteria develop in disease after the diseased condition has been engendered by some other agency, and that so far from being the cause of disease bacteria are "Nature's remedy to cure" it. Mr. Sherman Bigg supports his views by a chain of reasoning which is palpably defective, and makes statements which are demonstrably incorrect deductions from observed facts. He begins his letter by the statement that diversity of opinion inevitably tends to the advancement of science, which is in itself an *obiter dictum* which is open to question. It would be more correct to say that thoughtful criticism or difference of opinion, backed by carefully considered evidence, tends towards the advancement of science. He next states that "in many instances the presence of bacteria has been considered the sole proof of the existence of a specified disease." This again is an incomplete and an incorrect statement, since it is only when they conform to certain well-recognised critical conditions—the well-known criteria of Koch—that they are recognised as the causal agents in a given disease. It is precisely these conditions that the opponents of the bacterial origin of infective diseases, who are, by the way, usually out of touch with laboratory methods, lose sight of. It is well recognised that bacteria, even pathogenic bacteria, may be present in an animal organism without actually producing disease, since questions of dose, of virulence, and of resisting power of the host are all concerned, and what people are prone to do in this connexion in concentrating attention upon one factor in a complex process the result of the coincident action of several agencies is to lose sight of, or to ignore, the others. Mr. Sherman Bigg then makes the assertion that "bacteria do not exist in the early stage of disease." The only evidence offered in support of this statement is that bacteriological investigation sometimes fails to establish the specific nature of the disease in some cases until the diagnosis is established by other means. The further assumption is then made, that since pathogenic bacteria "are constantly being inhaled or swallowed without producing any evil result," bacteria cannot flourish in a healthy subject and can only develop in diseased surroundings, and that therefore bacteria are beneficent agents combating the morbid processes. This assumption ignores all the interesting observations which have been made regarding the action of pathogenic bacteria, the isolation of toxins from them, the genesis of disease in animals by inoculation of pure cultures, and indeed the whole of the carefully devised experiments which have resulted in such great advance in our methods of recognising, treating, and preventing infective diseases. We draw attention to Mr. Sherman Bigg's letter, because a similar attitude of mind towards bacteriology and its achievements is not so very uncommon. In spite of the great advances made by the science in the comparatively short space of time which has elapsed since its inception, it should be remembered that it is yet in its infancy, and instead of casting doubt upon its fundamental relation to the pathology of infective diseases, because in certain cases the methods so far evolved as regards diagnosis and treatment may be disappointing, it is better to wait for improvements in these and meanwhile to utilise the undoubted advantages which it has afforded us, and in any case to avoid disparaging those advantages without a careful and critical examination of all the material available.

THE PRESENT PANDEMIC OF PLAGUE.

A VALUABLE report has just been drawn up by Assistant Surgeon-General J. M. Eager, of the Public Health and Marine Hospital Service of the United States, and issued in the form of a pamphlet of 30 pages by the United States Treasury Department, tracing the lines of march taken by bubonic plague during the past 14 years. The revival of plague dates from the year 1894, when it escaped from the remote endemic focus of the disease in the province of Yunnan, China, eventually reaching numerous countries in all quarters of the globe, and in many instances becoming established in defiance of most carefully planned preventive measures. It first reached Canton and then began a series of ramifications that have since become world-wide. All classes among the native population suffered and rats were observed to be affected. In the year 1896 the attention of sanitarians was focussed on the threatening epidemic by the menacing appearance of the disease in Bombay. Although the source of this outbreak is uncertain it is probable that it was imported from Southern China. Notwithstanding considerable opposition founded on the religious prejudices of the native population active sanitary measures were adopted, but these had to be modified later owing to the civil disturbances provoked by the violation of caste distinctions. In the same year the disease reappeared in Hong-Kong and in Canton and two cases occurred at St. Petersburg. In 1897 the Bombay Presidency suffered from a more severe epidemic, resulting in 55,000 deaths, and the disease was present in the Punjab, at Karachi and Madras, and at the Turkish seaport of Jeddah where it was introduced by pilgrims. In 1898 the number of plague cases and deaths in India as compared with the preceding year was more than doubled, great increases occurring in Bombay, Rajputana, and the Punjab. The Presidency of Madras and the State of Hyderabad were invaded and the disease, extending far from its endemic home, reached Madagascar and Mauritius. The spread of the plague westward by Mussulman pilgrimages led at this time to the improvement of quarantines and the prevention of clandestine pilgrimages. Plague continued to increase in India in 1899, 135,000 deaths being reported, and from Hong-Kong it spread to the Straits Settlements. In Europe it visited Portugal, Russia, and Austria, and in South America it reached Paraguay, Brazil, and Argentina. In the year 1900 the disease was present in every quarter of the world, but it was less prevalent in India than in the previous year. Australia then became a plague centre and has lodged the disease ever since. Several notable extensions of the disease took place in Europe, cases being reported at Oporto, Glasgow, London, Cardiff, and Bremen. In 1901 the disease in India increased threefold, 278,000 deaths being recorded. The further history of plague is largely a chronicle of intra-continental expansion, the disease having become established in every continent. It continued to increase alarmingly in India until 1904, when it caused over 1,000,000 deaths. In the same year it was reported at Aden and in Siam, China, Japan, Uralsk, Egypt, South Africa, Mauritius, New Zealand, Australia, the Philippine Islands, South America, and of the alimentary canal. I have been particularly careful in my inquiries to ascertain the previous history, and in no case have I been able to suspect the sequence of simple inflammation and cancer in the intestine.

At the time when the patients came under observation it was only possible to excise the growth in five cases. Suppuration, adhesions to the posterior abdominal wall, to the anterior abdominal wall in one case and the small intestine were the reasons why extirpation could not be performed. I have traced two cases of excision. One was operated upon six years ago and is now in good health. In this the whole cæcum, ascending colon, and a part of the transverse colon with the lower ileum were removed. The second case, a less extensive resection of the colon, is well two years after.

Three cases of anastomosis I have been able to trace. Two died in five and seven months respectively. The third is alive but very weak nine months after the operation.

The clinical characters of growths elsewhere than in the cæcal region.—Age incidence.—The youngest was 15 and the oldest 89 years of age. Arranged in decades the numbers were as follows:—

Under 20 years	1 case.
Between 30 and 40 years	5 cases.
,, 40 ,, 50 ,, ...	10 ,,
,, 50 ,, 60 ,, ...	17 ,,
,, 60 ,, 70 ,, ...	15 ,,
,, 70 ,, 80 ,, ...	6 ,,
Over 80 (89) years...	1 case.

The sexes were about equally affected. There were 29 male and 26 female cases.

Of the 55 cases, I have been able to learn the previous history of 46. In eight of them there was a history of long-continued constipation. In three this had been present practically the whole lifetime. In the remainder it had been present for some years. But constipation was the only feature in these. It was never associated with any pain, diarrhœa, or hæmorrhage, neither was there any symptom elicited suggestive of a simple stricture. In other words, I have not traced in any case the relationship between malignant disease and simple inflammation of the bowel.

The onset of symptoms could practically in all cases be dated with precision. It invariably affected persons in otherwise good health with the exception of those who suffered from chronic constipation, and this was not regarded as anything other than normal by these patients. In a few cases the onset was not quite so definitely fixed. The patients described their symptoms as of a few weeks' or months' duration. But in by far the majority of cases the onset was more or less abrupt and its time of occurrence could be fixed with great precision. The symptoms of cancer are, of course, those which are directly dependent upon a progressive narrowing of the lumen of the bowel and the consequent hypertrophy of the gut above. Recurrent spasms of pain, gurgling of flatus as it is forced through the stricture, the discomfort caused by the inhibition of free passage of intestinal contents, anorexia, gradual failure of health and weight, and a progressive difficulty in the evacuation of the bowels are the main features. The hypertrophied gut above the stricture may be felt, or might be brought into prominence by a little gentle rubbing of the abdominal wall. This ought to be an early sign of a progressive stricture. Such symptoms were in general present in this series. They are all familiar and require no special comment. There are other clinical characters of which brief mention may be made. These are (1) the characters of the motions, and (2) the presence of an abdominal tumour.

1. There is constipation in the majority from the very commencement of the illness. But in a few this has not been so. In this series in about one-ninth this was said not to be present until some time after other symptoms. But in all it sooner or later was present. It may be that the bowels do not move daily or every other day, but what is of equal importance is that the quantity of fæces passed is distinctly less than normal. When the stricture relaxes and allows of a passage once more these catarrhal products are hurriedly rushed along and the result is that several loose motions may be passed for a day or so. Such motions may contain mucus and even blood. This was not a common symptom in this series. It is what is generally referred to as alternating constipation and diarrhœa. Constipation was the characteristic and diarrhœa the exception. When such spurious diarrhœa occurred it was unusual to have more than two or three attacks, and it would be very misleading to give as a symptom of cancer of the colon alternating constipation and diarrhœa. Apart from this diarrhœa mucus was observed in the motions on five occasions. Four of these were growths in the pelvic colon and in one the growth was at the splenic flexure. Blood in the motions was absent in the majority of cases. By this is understood visible blood; in no case was a microscopical or chemical examination made to determine its presence or absence. In one in the transverse colon, two at the splenic flexure, and in only 14 out of 37 growths in the pelvic colon was blood noted. In all it was particularly asked for and the stools were examined whenever possible.

2. *A palpable tumour.*—A tumour was by no means alway felt. Its presence will depend upon its situation, its size, and the state of distension of the abdomen. When the abdomen was not too distended to permit of examination a tumour was felt in this series as follows. In two cases out of three at the hepatic flexure, every case (three) at the transverse colon, in three cases out of seven at the splenic flexure, and in seven cases out of 22 in the pelvic colon. In two additional growths in the latter region a mass of undetermined connexions was felt through the vagina. A tumour was palpable therefore in 15 cases out 35 in which the condition of the abdomen permitted of examination—that is, in about 43 per cent. of cases.

The duration of the symptoms of incomplete intestinal obstruction varied considerably before becoming complete. In one the earliest symptom was acute obstruction. No previous history of intestinal trouble could be elicited in this case. The patient was first seen when obstruction had been present for three days and the abdomen was generally distended without evidence of the site of obstruction. That the obstruction was chronic was easily seen from the hypertrophy of bowel. Compensation had been so well maintained that previous to the sudden obstruction there had been no trouble whatever. In two further cases the onset was ten and 12 days previously with an attack of subacute obstruction which yielded to simple measures. Obstinate constipation was present during the succeeding few days which culminated in complete obstruction. Obvious bowel hypertrophy of some duration was present in these cases. The duration of symptoms in the others was from two months to three years. About one-third during this period had suffered from one or more attacks of threatened obstruction which had yielded to aperients or enemata. It may be mentioned that in many (about two-fifths) the administration of frequent and strong aperients had probably actually produced the final obstruction. This may be considered as a warning.

In considering the causes of the terminal obstruction it may be said that there was not one case of volvulus of the bowel above nor one of intussusception, both of which are given as occurring sometimes. In one case the obstruction seemed to be enhanced by the kinking and adhesion of a lengthy loop of bowel above the growth. In two others it was probable that an abscess around the growth determined in part the obstruction. In no case could the impaction of a foreign body or fæcal accumulation be said to be the cause of obstruction.

The onset and progress of the terminal obstruction varied somewhat. In three acute dilatation of the cæcum was the earliest sign. So sudden was this and so pronounced was the distended cæcum that a volvulus or some other mechanical acute obstruction might have been suspected. All three cases gave a comparatively short history. In three in which the symptoms had been by no means urgent but merely those of chronic obstruction an acute dilatation of the colon occurred. The abdomen rapidly became swollen, vomiting was profuse and foul-smelling, and collapse was decidedly marked. Compensation in these had been maintained up to a certain point and then it would appear that the colon suddenly gave out. Possibly antiperistalsis may explain the cases of acute dilatation of the cæcum. In the majority the obstruction was more slowly progressive. The abdomen more slowly distended due to the more or less gradual distension it would be in exposing themselves to the risk of infection at a time when there would be no likelihood of their taking it if they held aloof from that one particular case. The idea of a medical practitioner or nurse running away to a non-infected area in times of epidemic is, we hope, inconceivable. But we are ready and proud to admit that cases of special medical heroism in such times do occur which are particularly worthy of such practical recognition as Mr. Carnegie offers. Ready instances may be quoted from Ireland where it happens often that a district medical officer has to treat typhus fever with no available assistance and perhaps in opposition to an ignorant and frightened peasantry. Many will recall the death of William Smyth seven years ago after his splendid struggle waged against the waves of Donegal and still more against the human cowardice that refused him and his brave colleague, Dr. McCarthy, any aid in rowing over a crazy boat to fetch the patients suffering from typhus fever under his charge from their hovels on Arranmore Island to the hospital on the mainland where they could be treated properly. It will be remembered how Smyth contracted the disease and died, a martyr to duty, if ever there was one. At that time in appealing for a memorial fund to help his widow and eight children we wrote: "If he ever knew that he had accomplished the work that he set himself to do he died without thought of the praise his deed would earn for his memory but only with the consciousness that he was leaving those he loved to face the world before he had time to make provision for them." That bitterness may now be spared to the medical man whose life shall be required of him as the price of his admission to the ranks of such heroes. The profession will be no less grateful that their brothers who have suffered severely in the cause of science or humanity but who have escaped with their lives will be remembered under the benefits of Mr. Carnegie's new trust fund, and in this connexion there will be a general hope that its administration may have the case of Mr. J. Hall-Edwards, whose civil list pension is incommensurate with his injuries, brought prominently before them. Whilst he and many others have sustained grievous hurt in the legitimate pursuit of science it is perhaps well to point out that some have to show less honourable because unnecessary scars. Impetuous youth, especially, in medicine as in all other fields of effort, will continue to mistake carelessness for courage and foolhardiness for devotion to duty. We hope that this fund may not seem to put a premium upon such professional rashness, and we could almost wish that its trustees would debar from its benefits any who, for example, suffer direct infection in a bacteriological laboratory through habitual disregard of common-sense precautions, or who seek to remove diphtheritic membrane from a tracheotomy tube by sucking it, a proceeding which is quite unnecessary when proper provision has been made for emergency, but one which seemingly has an evergreen appeal to popular sentiment.

CATS AS PREVENTERS OF PLAGUE.

THE *Indian Medical Gazette* for August prints another article by Lieutenant-Colonel Andrew Buchanan, I.M.S., advocating the up-keep of cats as the best method of counteracting plague. The paper is rather discursive, but it nevertheless contains a large amount of interesting and valuable information. During the past plague season, says the writer, there have been epidemics of plague in 54 towns and villages in Amroati district, and investigations have been made in nearly all of these to find how far the presence or absence of the disease could be accounted for by the absence or presence of cats. The investigations were made by "assistant surgeons, hospital assistants, tahsildars, patwaris, police, vaccinators, and others," but the results were verified in a general way by Colonel Buchanan himself. The reports that he received were too numerous and too voluminous for the inclusion of even a brief outline of them all in a short paper, but it was, he said, "perfectly clear from a perusal of them that the keeping of cats is *the* method of preventing plague." To all other methods, in his opinion, there are objections more or less grave, but to the keeping of cats there are next to none. Hindus object to killing rats because the rat is the *Sowari* (means of locomotion) of their god Gunpati. Some of them even catch rats in order to let them go free in the fields. Jains, it is true, object to cats, but in small towns they are few in number and in villages they are rarely to be found. In Saur plague was severe among the Bhowani Dhers, but the Mallies, who keep buffaloes and consequently cats, which are attracted by the milk, escaped completely. The Dher is not allowed to keep cats because when a cat has kittens or dies in his house he is put out of caste. Some Dhers living in wattle huts escaped the plague entirely. This at first puzzled Colonel Buchanan until he found that rats do not harbour in that kind of structure. Other Dhers living in mud huts were severely visited by the plague. So greatly was the Dher community impressed by these facts that now many of them keep male cats, thus avoiding the caste penalty so far as the birth of kittens is concerned. "It is a great pity," continues Colonel Buchanan, "that the members of the recent Plague Commission did not make some experiments on the cat as a rat destroyer. Neither the members of the Plague Commission nor Professor Haffkine in his recent lecture on the 'Present Methods of Combating Plague' have, as far as I have seen, said a word about the cat. One member of the Commission gives a whole page of figures to show that, in spite of vigorous efforts for a whole year, the number of rats could not be considerably reduced by traps. He does not tell us whether there was one trap or fifty, but I can assure him that his whole argument would be completely upset if a few cats were introduced." Colonel Buchanan looks upon rat destruction and inoculation as temporary expedients capable in certain circumstances of yielding useful results but both in the main hurtful because they distract attention from the only true remedy. "The more attention we give to inoculation," he says in conclusion, "the less we are certain to give to the only sound common-sense method of preventing plague—viz., the keeping of the natural enemy of the animal that is responsible for spreading the disease."

MORTALITY FROM TUBERCULOUS DISEASE IN THE UNITED KINGDOM.

THE annual report relating to 1907 recently issued by the Registrar-General for Ireland contains an interesting comparison of the relative death-rates from tuberculous disease in England and Wales, Scotland, and Ireland during the 43 years 1864–1906. A diagram in this report shows that in the year 1864 the death-rate from all forms of tuberculous disease was equal to 3·3 per 1000 of the estimated population in England and Wales and to 3·6 per 1000 in Scotland, whereas it did not exceed 2·4 per 1000 in Ireland. We referred to this diagram and to several other points which are raised in the communication which follows, but many of the remarks of our correspondent are interesting, so that we publish them in spite of the occasional repetitions. "In England and Wales the annual death-rate from tuberculous disease has steadily declined during the 43 years referred to, and had fallen to 1·6 per 1000 in 1905 and in 1906, this decline being equal to 51·5 per cent. In Scotland the annual death-rate from this one on each temple. Two morning applications gave her relief for the day, but as the pain came on again at night for three days she was treated twice a day, for nine days once a day, and for a few days longer on alternate days. Except for a few short attacks soon after treatment commenced she had no further pain.

In cases of bladder trouble it has not proved so successful in our hands as is reported from other sources, but one case is worthy of note.

CASE 5.—J. K., a hard-working, sensible girl, had been troubled all her life with frequent micturition, having during cold and damp weather to micturate every ten minutes. For some years past she had to stop from work during winter months. The whole trouble was purely nervous. She had had various medical treatments and had been in nursing homes, receiving little or no benefit. We applied one pad over the lumbar region and the other two well down over the pubes, taking care that they did not touch each other and (as in all cases where it is suspected that the nerves are at fault) the current was used as rapid as possible. This patient improved at once and was able to keep to her work all the winter, but if the treatment stopped for a fortnight she began to relapse, which resulted in her coming for treatment two or three times a week during the cold months.

This form of electrical treatment gives relief in pains of rheumatoid arthritis but we have not been able to give it a fair trial in this class of disease. We ought to mention some difficulties that may arise in treatment. If there is the least break in the cuticle, as a scratch or pimple, the current is painful at this point; such places are best protected with rubber strapping. Laparotomy scars also often give considerable pain during treatment.

The following is a tabulated list of the cases which have been treated with this combination wave-current:—

Condition.	Result.
Constipation with atony of colon.	Recovery 88 per cent.
Alternating constipation and diarrhœa.	Unsatisfactory.
Nervous debility.	Recovery 70 per cent.
Alcoholic neuroses and general paralysis of the insane.	*Nil.*
Rheumatoid arthritis.	Appears to be beneficial.
Dyspepsia.	" " "
Enuresis.	Improvement while under treatment 80 per cent.

NOTES ON A CASE OF ACCIDENTAL POISONING BY CHLORIDE OF ANTIMONY.

BY J. MIDDLETON, M.D. EDIN.

ON account of the clinical features presented, not less than the comparative rarity of accidental poisoning by the salts of antimony, it appears desirable to place on record the following case which recently came under observation.

About 4 P.M., during the temporary absence of the mother in an adjoining part of the house, a male child, aged 16 months—the child is said to have walked since he was nine months old—crawled from his cradle placed on the floor, crossed the apartment, and mounting on a chair managed to reach the top of a dresser standing fully four feet high, near the centre of which stood a firmly-corked bottle containing a preparation which the father, a shepherd, was in the habit of using as a dressing for the feet of sheep affected with foot-rot. Withdrawing the cork, the child put the bottle into his mouth and swallowed a portion of its contents, whereupon the mother was attracted by his screams. It is, of course, very difficult, if not absolutely impossible, to estimate with any measure of accuracy the actual amount of the poison swallowed, but making full allowance for what was spilt on the child's clothes and about him, and having regard to the father's estimate of the quantity contained in the bottle, which had been reduced by fully three tablespoonfuls, it appears probable that the child must have swallowed at least two teaspoonfuls of the liquid. About half an hour before taking the poison the child had a small quantity of milk and a little bread and butter.

Immediately upon discovering what had happened the friends administered hot salt and water and continued to do so at short intervals till my arrival. I then learned that the child had vomited pretty frequently and that the vomit which at first appeared to contain little else than particles of bread and curdled milk, gradually changed to a dark coffee-ground appearance, and this statement I was able to confirm by an examination of the earlier and later vomits, all of which had been retained for inspection. The bottle from which the child had drunk was found to be correctly and carefully labelled "butter of antimony," and still contained about three ounces of a dark orange-coloured fluid, a few drops of which when added to water yielded a whitish-yellow precipitate. When seen about an hour after the poison had been taken the child presented the following symptoms. He lay in a heavy, drowsy state extended on the knees of a neighbour, his head being thrown forcibly back, from time to time exhibiting a struggling and choking sensation, clutching at and complaining of pain in his throat. The lower limbs were alternately forcibly extended or drawn upwards and flexed over the abdomen. Both upper and lower extremities were markedly and persistently cold. The pulse was barely perceptible; the pupils were widely dilated and inactive and there were frequent muscular twitchings. The general condition, indeed, was one of pronounced collapse. The chin, lips, tongue, the whole interior of the mouth, and the fauces were whitened in the same manner as by the action of strong carbolic acid and there was some difficulty in swallowing, accompanied by considerable regurgitation from the nares. There was a very marked tendency to doze but the child could be readily roused to take fluids, his thirst being intense. The vomiting of dark coffee-ground matter continued, though at lengthening intervals, during the greater part of the following day and diarrhœa presenting similar characteristics set in about 16 hours after the poison had been taken and persisted for fully 48 hours. Even after the diarrhœa was checked the fæces continued for some days to present a preternaturally dark colour. When the vomited matter was submitted to Reinsch's process abundant evidence was afforded of the presence of antimony, and the urine when similarly treated yielded traces of the metal during the two following days The child was fed with milk and white of egg for the first 24 hours, after which barley water or rice water was added. A mixture containing equal parts of compound tincture of cinchona and tincture of calumba was given first at short and later at gradually lengthening intervals, and in about a week from the taking of the poison the child was apparently in his normal health and taking his customary food.

Manorhead, Stow.

A CASE OF RHEUMATIC HYPERPYREXIA.

BY THOS. E. B. MEYLER, L.R.C.P. & S. IREL.

THE rarity of hyperpyrexia during the course of acute rheumatism in children makes any example worth recording.

The patient, a boy aged nine years, was seen by me for the first time on August 30th, 1908. For the past seven weeks he had complained of a stiff neck, which was painful on movement, and of slight pain in the legs, but he was able to attend school. I was called in because when he awoke in the morning he could not move the left arm. I found him in bed, free from pain except in the neck which was not swollen or tender. The pulse-rate was 136 and the temperature was 99·6° F. The tongue was clean and the patient was perspiring. The apex beat was in the left nipple line, about one inch lower than the normal. Impulse was forcible but there was no thrill. The aortic second sound was clear. There was a loud mitral pre-systolic murmur and a systolic murmur was well heard at the left scapular angle. The lungs were healthy. The left upper extremity was completely paralysed and flaccid. The other limbs were not affected. The urine was high-coloured and was free from albumin. There was no change in the condition of the patient until Sept. 3rd, when I was hastily called to him at 6 A.M. I found him deeply comatose and breathing stertorously. The pupils were contracted, the face was cyanosed, and the skin was hot and very dry. The temperature was 109·2° and the pulse was uncountable. Violent purging took place. Ice not being available cold sponging was used, but the patient died in an hour, the temperature rising to 110° just before death.

Experience has shown that hyperpyrexia is most frequent in first attacks of rheumatism, also in cases which run a mild course. Both these points are illustrated by this case.

Chevening road, W

All the symptoms continued to show improvement. By the next morning—60 hours after the first carbolic injection—the pain in the head was much better and the mouth could be opened and the neck moved; the reflex spasms, too, had disappeared, also the photophobia, and the pain in the foot. Two more injections were given on that day and one on each of the two following days, at the end of which time—i.e., five days from the commencement of the treatment—all the distinctive symptoms of tetanus had disappeared. The urine was carefully examined all through and no signs of carbolic acid poisoning were detected. The patient was able to leave her bed in a few days, when general lassitude and marked weakness of the jaw and right side only remained. The carbolic treatment of tetanus, combined with the administration of chloral or antitetanic serum, has of late attracted a certain amount of attention, and is generally associated with the name of Professor Baccelli, though it does not seem certain that he was the first to employ it. It has the great advantage of being always at hand, and although the hypodermic method of administration is usually adopted, the solution may be given by the mouth or per rectum. Dr. Osherovski more than 13 years ago reported in a Russian medical journal[1] the case of a man who ten days after a gunshot wound in the leg began to show symptoms of tetanus which in spite of huge doses of morphine and chloral increased in severity for another ten days. Carbolic acid was then tried. Of this a 2 per cent. solution was employed and 12 drops were administered hypodermically every three hours. In two days there was a marked improvement and the patient was convalescent after 28 injections. Dr. Shrana[2] used a 2 per cent. solution of carbolic acid successfully in the case of an Arab who developed tetanus after receiving a wound which had been dressed with cobwebs and washed with urine. Mr. A. B. J. Eddowes of Loughborough reported in THE LANCET, Jan. 16th, 1897, p. 168, the case of a man who had received a punctured wound in the great toe of the left foot which suppurated and was followed in three weeks by stiffness of the jaw, which rapidly became more marked and a week later, in spite of treatment by bromides and chloral, convulsions occurred. Hypodermic injections of 5 minims of a 2 per cent. solution of carbolic acid were then given night and morning for four days, when the patient's condition was greatly improved. He made a good recovery. Professor Baccelli[3] has treated a considerable number of cases with carbolic acid. He seems at first to have employed a 1 per cent. solution, but afterwards to have increased the strength to 2, 3, 4, and even 5 per cent. Symmers[4] gives a review of 75 cases treated by carbolic acid with a total mortality of only 23 per cent. Felici and Maremmi[5] also publish successful cases.

THE LADIES' HOME AT CANNES.

SITUATED above the town of Cannes, in the healthiest surroundings, the Ladies' Home, which was established a quarter of a century ago with the object of affording rest and change of scene to British and American ladies of small means who are in feeble health or are suffering from the effects of overwork, continues to fulfil the purpose for which it was founded. The inmates, who must not be in actual ill health or invalids requiring constant nursing, pay their own fares out and home and £1 per week for maintenance. Mental cases or cases of an unfavourable tuberculous character are not admitted. A private room is provided for each inmate, while there are a common dining-room and a sitting-room and also a private chapel. The home is under the supervision of two British physicians of Cannes whose services are given gratuitously during the season which extends from Nov. 1st to the end of April. There are also an experienced lady superintendent and a trained nurse on the staff. The accommodation provided is for 34 ladies. This institution does excellent work, and is entirely supported by subscriptions and donations of the British and American residents and visitors to Cannes. It deserves wider recognition and it should only be necessary to make the existence of the institution better known to the medical profession of this country to insure an increased financial support and an increased supply of fitting candidates. Application should be made to Miss Hankey (Hôtel des Anglais, Cannes, during the winter, and the Palace, Much Hadham, Herts, in the summer), who will be pleased to give full particulars.

THE CHOLERA IN RUSSIA.

THE extension of cholera to the Black Sea has affected several southern Russian ports. The disease has been officially reported as having occurred recently at Odessa, Rostov, Kieff, Kherson, Kronstadt, and Ekaterinoslav; while newspaper accounts also mention its presence at Warsaw, Kertch, Taganrog, Theodosia, Nicolaieff, and Azov. Similar reports from St. Petersburg state that there is a decline in the number of cases, the daily returns now being well below 300. Whereas on Sept. 22nd the incidence had reached 419 cases with 177 deaths, on Sept. 30th 228 cases with 93 deaths were reported, the returns from the provinces showing a like decline. The disease has been chiefly confined to the poorer classes. It is to be hoped that this drastic lesson will induce the authorities of the Russian capital to instal a proper water-supply and drainage system throughout the city, even though they disregarded the even more terrible warning which the cholera gave them in the last decade of the last century. At the very least it may be expected that adequate provision of infectious wards may be made against the contingency of another outbreak. The reports of the overcrowding of dying patients and the deficiency of sanitary equipment are only redeemed by the accounts of the devoted service which the medical officers attached to the hospitals have given despite such grave disabilities. Concerning the etiology of the disease a correspondent has forwarded us the following curious communication from a relative resident in the neighbourhood of Minsk and Bobrinsk: "A doctor in Petersburg told E—— earlier in the year that there was sure to be a bad outbreak of cholera this autumn in the town as the influenza outbreak in the winter was always accompanied by colic and pain in the stomach, and he said whenever this happened there was always an outbreak of cholera the next autumn. True enough, it has come." Our correspondent asks if there can be some mysterious connexion between the two diseases. The observation is interesting but we are not aware that any causal relationship has been recognised by expert observers between the gastric form of influenza and cholera. It is perfectly true that severe epidemic enteritis is often the precursor of an outbreak of cholera in eastern countries, but it is more than probable that the name "choleraic diarrhœa" is simply an euphemism for the dreaded disease itself and that its employment to allay public anxiety has often been fraught with grave danger to a community which would otherwise have faced the evil squarely and taken early measures to mitigate its ravages. It is, however, quite legitimate to suppose that a number of persons whose powers of resistance have been weakened by a severe outbreak of influenza, especially when it has taken a gastric or enteric form, would afford an excellent soil for the development one on each temple. Two morning applications gave her relief for the day, but as the pain came on again at night for three days she was treated twice a day, for nine days once a day, and for a few days longer on alternate days. Except for a few short attacks soon after treatment commenced she had no further pain.

Manorhead, Stow.

A CASE OF RHEUMATIC HYPERPYREXIA.

BY THOS. E. B. MEYLER, L.R.C.P. & S. IREL.

THE rarity of hyperpyrexia during the course of acute rheumatism in children makes any example worth recording.

The patient, a boy aged nine years, was seen by me for the first time on August 30th, 1908. For the past seven weeks he had complained of a stiff neck, which was painful on movement, and of slight pain in the legs, but he was able to attend school. I was called in because when he awoke in the morning he could not move the left arm. I *found* him in bed, free from pain except in the neck which was not swollen or tender. The pulse-rate was 136 and the temperature was 99·6° F. The tongue was clean and the patient was perspiring. The apex beat was in the left nipple line, about *one inch lower* than the normal. Impulse was forcible but there was no thrill. The aortic second sound was clear. There was a loud mitral pre-systolic murmur and a systolic murmur was well heard at the left scapular angle. The lungs were healthy. The left upper extremity was completely paralysed and flaccid. The other limbs were not affected. The urine was high-coloured and was free from albumin. There was no change in the condition of the patient until Sept. 3rd, when I was hastily called to him at 6 A.M. I found him deeply comatose and breathing stertorously. The pupils were contracted, the face was cyanosed, and the skin was hot and very dry. The temperature was 109·2° and the pulse was uncountable. Violent purging took place. *Ice not being available* cold sponging was used, but the patient died in an hour, the temperature rising to 110° just before death.

Experience has shown that hyperpyrexia is most frequent in first attacks of *rheumatism*, also in cases which run a mild course. Both these points are illustrated by this case.

Chevening road, W.

account of them. At the risk of making these young men blush he would say that they had a very good opinion of them. They had won golden opinions during the four months they had been there and the report of Fleet-Surgeon Bassett-Smith to the Director-General stated:—

> In the past session considerable changes have been made in the instructional course, subjects of the greatest practical utility for surgeons in the navy have received extra attention, particularly the examination of recruits, management and treatment of venereal cases, and the administration of anæsthetics. They have also received practical demonstrations in shallow and deep water diving and in submarine vessels. I have to report that the surgeons have shown great interest in the subjects under their study throughout the course. They have been diligent in their work and have taken full advantage of the facilities for instruction which have been offered to them, much of which was new but of importance in their future career. In carrying out the professional duties required of them in the wards, the surgeons, as a whole, have received special commendation from the senior medical officers, having given general satisfaction. The following officers have been specially mentioned for zeal and ability—Surgeons Atkinson, Austen, Custance, Fisher, Hayes, and Rivers. For proficiency in anæsthetics Surgeons Atkinson, Austen, and Fisher are noted, and Surgeon Robinson for skill in radiography. Special reference is due to Surgeon Atkinson, who, assisted by Surgeon Custance, devoted much time and skill, with very considerable success, to the treatment of difficult cases with gonococcal vaccines.

Inspector-General Gimlette added that the naval medical officers could congratulate themselves very much on having so strong an addition to their professional forces.

Dr. Macnamara then presented the prizes as follows:—

Naval hygiene group.—Gold medal awarded to Surgeon A. T. Rivers, of Guy's Hospital, Surgeon A. R. Fisher being second.

Tropical medicine group.—Microscope awarded to Surgeon W. H. Edgar, of St. Mary's Hospital, Surgeon A. R. Fisher being second.

Practical analysis group.—Silver medal and books awarded to Surgeon E. L. Atkinson, of St. Thomas's Hospital, Surgeon J. S. Austen being second.

The order of merit on passing out of Haslar was:—

	Marks.		Marks,
1. A. T. Rivers	4662	9. G. H. C. Given	3766
2. J. S. Austen	4529	10. J. M. Hayes	3350
3. G. W. M. Custance ...	4353	11. P. B. Egan	3342
4. A. R. Fisher	4308	12. F. H. Stephens	3280
5. W. H. Edgar	4218	13. S. Bradbury	3235
6. E. L. Atkinson	4024	14. R. M. Riggall	3059
7. A. L. Robinson	3844	15. G. A. Bradshaw	2742
8. C. J. Aveling	3827		

Subsequently to presenting the prizes, Dr. MACNAMARA delivered the following address: "You will believe me when I say that I am honoured to take part in to-day's function. You are entering a great public service, the greatest, I think, the world has ever known. And in that great service you have been called to a peculiarly responsible function. Our bluejackets and marines are fine men—I think them finer every time I meet them. Their training is long and costly, and we cannot rapidly and cheaply replace them as we could do a hundred years ago. We call upon them even in peace times to serve their King and country in all climes and under conditions that are very often physically arduous and exacting. And whether duty calls them to the plague-stricken swamp, the fever-laden lowlands, or the frost-bitten coast their response is always a resplendent reflection of the traditions of the service to which they belong. Further, we can give them no choice as to their medical attendant. Therefore we are bound, as I think, to furnish them when they fall sick from hard campaigning, or exposure, or—may God forbid that it should come in our time—from the fiendish ravages of modern naval warfare, with the very best the country can provide in the way of medical and surgical services. And, Gentlemen, I want you and the medical schools generally to understand that, so far as the Admiralty is concerned, we mean to do it. We mean our hospitals to be well-found and our doctors as good as any in their great profession. But you on your part are bound to help us. You are bound to be ever up-to-date, keen and enthusiastic in your calling. You enter a field of practice second to none in width, variety, and interest. You must not only be ready to apply the latest knowledge for the curing of the ailing; you must also be alert with the most scientific measures for the prevention of disease. More than ever the safety of this far-flung empire depends upon the efficiency of the fleet. And, certainly, more than ever, the efficiency of the fleet depends upon the man behind the gun. And behind that man you stand, ready to play your arduous and responsible part. Gentlemen, I have always heard that the four great Nelsonic qualities which go to make up the efficiency of the naval officer are: (1) fearlessness of responsibility; (2) fertility of resource; (3) power of initiative; and (4) self reliance. How acutely they apply in his field of duty to the naval medical officer! Do your part and we will do ours. Your careers are in your own hands. Ample opportunities will be afforded you to continue your studies by post-graduate courses of instruction. The school of tropical medicine will be opened to you periodically and the fresh discoveries of medical science will be found waiting for you and at your disposal on your return from commission. I hear men spoken of as 'having had all the luck.' But, behind that luck, I have invariably found tireless patience, indomitable perseverance, and unquenchable enthusiasm. So far as we are concerned we mean that zeal and enthusiasm shall receive all the encouragement we can give them. Remember, that in your profession the one fatal thing is to get rusty. And rusty you will get if you fail to remember that, even on the day of your retirement, you are barely on the threshold of knowledge. If I had the choice I think I would prefer a natural death to the ministrations of a rusty doctor. You are privileged to follow, let me also say, in the footsteps of great and distinguished men. Professor Huxley entered the service as a naval medical officer in 1846 and served the first part of his time in this very hospital. Sir Joseph Hooker, the botanist, director of Kew Gardens from 1865 to 1885, and President of the Royal Society 1873–77, served officially as an assistant surgeon in the *Erebus* during Ross's voyage in the Antarctic Seas. Sir Joseph Hooker, I may say, is still a naval medical officer on the retired list. Smollett, the novelist, entered the Navy as a doctor in 1739, and served in the operations against Carthagena in 1741. Thomas Dover, famous for ever through 'Dover's powders,' sailed in 1708 on a privateering voyage round the world during which he found Alexander Selkirk on Juan Fernandez and brought him home. Sir Gilbert Blane served in the Navy under Rodney, and Charles Darwin was also in the Navy as a naturalist on board the *Beagle*. And to this incomplete record I might very well add the names of naval medical officers whose gallantry on the field of action has won the Victoria Cross and many distinguished service Orders. But I know you too well to appear even to make a parade of this. Gentlemen, good-bye. Permit the son of a man who fought in the trenches before Sevastopol, one who began life in a British barrack-room, and one who well knows the gentleness, the tender sympathy, and the generous-heartedness of the medical men of both services, to wish you God-speed in the noble calling which you have elected to follow."

At the close a vote of thanks was accorded to Dr. Macnamara for his attendance, on the proposition of the Director-General.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN 76 of the largest English towns 8140 births and 4115 deaths were registered during the week ending Sept. 26th. The annual rate of mortality in these towns, which had steadily declined in the five preceding weeks from 15·8 to 13·9 per 1000, further fell to 13·2 during the week under notice. During the 13 weeks of the past quarter the annual death-rate in these towns averaged 13·4 per 1000, and in London the mean rate in the same period did not exceed 12·5. The lowest annual death-rates in these towns during the week under notice were 3·6 in Walthamstow, 6·2 in Hastings, 7·1 in Bury, and 7·4 in Aston Manor; the rates in the other towns ranged upwards, however, to 18·8 in Blackburn, 18·9 in Tynemouth, 19·8 in Warrington, and 20·0 in Salford. In London the death-rate during the week was 13·3 per 1000. The 4115 deaths from all causes in the 76 towns showed a further decline of 222 from the decreasing numbers in the four preceding weeks, and included 527 which were referred to the principal epidemic diseases, against numbers declining from 1343 to 677 in the four previous weeks; of these 527 deaths, 353 resulted from diarrhœa, 42 from whooping-cough, 39 from diphtheria, 35 from "fever" (principally enteric), 31 from measles, and 27 from scarlet work has been carefully revised and the necessary corrections and additions have been made so as to bring the whole fully up to date. The latest researches in regard to the etiology of sleeping sickness and of yellow fever have been duly recorded, and changes have been made in the sections dealing with the examination of the nervous system and in the description of the diseases of the blood. Entirely new matter has been introduced on the subject of opsonins and opsonic methods, paratyphoid fever, kala-azar, senile paraplegia, diseases of the sympathetic nervous system, diseases of the muscles, heart block, Vincent's angina, congenital hypertrophic stenosis of the pylorus, and ochronosis. An interesting account is given of Stokes-Adams disease and the part which is played in its pathology by the bundle of His is carefully explained. The sanatorium treatment of pulmonary tuberculosis is scarcely described at sufficient length. The rules which govern exercise, both as regards nature and amount, could with advantage be given more fully in future editions, but the symptomatic treatment is more usefully detailed.

Students will find this manual a satisfactory one to read for examination purposes but its employment must of course be supplemented by practical work in the wards and out-patient rooms. For practitioners the work will prove of value for rapid reference and for refreshing the memory when they are discharging the actual practice of their profession.

Cataract Extraction. By H. HERBERT, F.R.C.S. Eng., late Lieutenant-Colonel I.M.S., Professor of Ophthalmic Medicine and Surgery, Grant Medical College, and in Charge of the Cowasjee Jehangir Ophthalmic Hospital, Bombay. London: Baillière, Tindall, and Cox. 1908. Pp. 391. Price 12*s.* 6*d.* net.

THIS is a book which no ophthalmic surgeon should fail to read. It gives in considerable detail the methods and opinions of a surgeon who has had great experience in the extraction of senile cataract amongst the natives of India, a country notorious for the prevalence of the disease and one to which we are already indebted for many valuable communications on this branch of ophthalmology. We are told in the preface that the volume embodies an experience of about 5000 extractions, "a comparatively small experience for an ophthalmic surgeon of standing in India." Such a remark is likely to prejudice the reader adversely at the outset, for it savours somewhat of unnecessary modesty. How many surgeons in India have performed more than 5000 extractions?

The first chapter deals with operable cataract, a description of its forms and stages, and the question of artificial ripening. In discussing the conditions which determine fitness for operation we are told that it is accepted that infection of the conjunctiva from the nose by way of the lacrymal passage does not take place, an unduly dogmatic statement. In dealing with the general health in the same connexion no reference is made to the condition of the mouth and teeth; the dangers of oral sepsis should not be ignored in an exhaustive treatise of this nature. It is interesting to note that the author's measurements of lenses show that the average normal lens of the native of Bombay is probably appreciably smaller than that taken from Priestley Smith's measurements in England, in correspondence with the poorer average physique in Bombay. On Priestley Smith's theory this would account for the comparative rarity of primary glaucoma. The description of the operation which the author favours occupies 136 pages. After a brief account of the various kinds of section which have been advocated in the past the instruments and irrigators are described. In addition to preliminary sterilisation by boiling the cystitome, forceps and irrigator nozzle were frequently sterilised in the flame. Cocaine, with or without adrenalin, was used for rendering the eye anæsthetic. During the operation a mouth-screen of flannel stretched over a wire frame was employed. Two points require special mention among the initial steps. In addition to the great prevalence of chronic conjunctivitis the natives of Bombay apparently produce an enormous amount of Meibomian secretion. Expression of this secretion with the fingers was therefore invariably performed. Great stress is laid upon the importance of irrigation of the conjunctival sac with perchloride of mercury lotion. Lieutenant-Colonel Herbert used a strength of 1 in 3000 applied for from one minute to one and three-quarter minutes. The usual operation was the ordinary sclero-corneal section with a conjunctival flap combined with iridectomy. The individual steps are described at length and in great detail; they differ little from those commonly adopted. A single vertical incision with a cystitome was generally employed for opening the capsule; the lens was expressed with a tenotomy hook. Irrigation to remove lens cortex was apparently used fairly frequently by means of a simple syphon douche containing 0·7 per cent. salt solution. At the conclusion of the operation the curette was passed lightly over the whole of the palpebral conjunctival surface to remove mucus.

The third chapter is devoted to expulsive hæmorrhage and vitreous accidents. The fourth chapter treats of variations in procedure and their value. Noteworthy here are the indications for the use of Czermak's downward section with subconjunctival pouch and of simple extraction; the latter method was seldom adopted though the author was using it more often towards the end of his time in Bombay. Ophthalmologists will read with interest Lieutenant-Colonel Herbert's remarks on extraction of the lens in its capsule. The revival of this method, inaugurated in India by Mulrony at Armitsar in 1890, has received an impetus from the work of Smith at Jullundur, some account of which has been given in THE LANCET recently by this surgeon.[1] The author's strictures on Smith's claims, contained in the first paragraph under operative procedure on p. 253, however true they may be, coming from a colleague in the same service had better been expressed otherwise. We think that the advantages and disadvantages of the operation are discussed judicially and with a proper sense of the gravity of the subject. The conclusion that the method is one of strictly limited applicability is, we consider, inevitable, and will ultimately be the generally accepted view.

In the matter of asepsis the author is to be congratulated upon his results: he had no suppurations amongst the last 1655 extractions and only one in the previous 1172. Panophthalmitis with total loss of the eye is clearly meant, for cases of slighter infection are recorded. It is difficult to follow up cases in India, and perhaps the results would appear less favourable if this could have been done more fully. All ophthalmic surgeons are cognisant of cases which go wrong in spite of minute precautions, and we are strongly of the opinion that the author is extremely ill-advised to have allowed the following sentences to occur in his book: "The general trend of recent work is to fix the responsibility for infective accidents very definitely upon the surgeon. In the not distant future we may find this responsibility recognised by the patient and possibly upheld in law courts." Surely this is going much farther than is warranted by the facts, and is the more deplorable in that it is likely to be quoted in the law courts as the authoritative opinion of an expert.

The analysis of visual results does not reveal such exceptional statistics. In 1262 cases operated upon in 1905–06 bad results—i.e., loss of vision or vision of moving bodies—only

---

[1] THE LANCET, August 15th, 1908, p. 452.

1st South Midland Mounted Brigade Field Ambulance: William Henderson Stephen to be Captain (dated July 31st, 1908). Thomas Henderson Forrest to be Lieutenant (dated July 31st, 1908).

3rd East Anglian Field Ambulance: Surgeon-Captain Daniel Mowat, from the 3rd Volunteer Battalion, The Essex Regiment, to be Major (dated April 1st, 1908). Surgeon-Captain Josiah Oldfield, from the 1st Volunteer Battalion, The Essex Regiment to be Captain (dated April 1st, 1908).

2nd Home Counties Field Ambulance: Lieutenant Albert Richard Henchley, from the Eastern Command, Maidstone Companies, Royal Army Medical Corps (Volunteers), to be Major (dated April 1st, 1908). Lieutenant William Henry Flint, from the Eastern Command, Maidstone Companies, Royal Army Medical Corps (Volunteers), to be Lieutenant, with precedence as in the Volunteer Force (dated April 1st, 1908). Herbert Stanley Hollis to be Lieutenant (dated April 27th, 1908). David Livingston Hamilton (late Surgeon-Lieutenant, 4th Volunteer Battalion, The Manchester Regiment) to be Lieutenant (dated May 5th, 1908). Raby Montague Grogono to be Lieutenant (dated May 5th, 1908).

3rd London Field Ambulance: Quartermaster and Honorary Captain James W. Bennett is granted the honorary rank of Major (dated August 31st, 1908).

1st West Riding Field Ambulance: James Mackinnon to be Lieutenant (dated April 1st, 1908).

3rd Wessex Field Ambulance: Alexander Milne-Thomson (late Surgeon-Major, the 9th New Zealand Mounted Rifles, South African Field Force) to be Lieutenant (dated July 6th, 1908).

1st London General Hospital, Royal Army Medical Corps: The undermentioned to be officers whose services will be available on mobilisation (dated July 31st, 1908):—To be Lieutenant-Colonels: Norman Moore, William Harrison Cripps, Samuel West, and William Bruce Clarke. To be Majors: Joseph Arderne Ormerod, Anthony Alfred Bowlby, C.M.G., Wilmot Parker Herringham, Charles Barrett Lockwood, Howard Henry Tooth, C.M.G., D'Arcy Power, Archibald Edward Garrod, and Holburt Jacob Waring. To be Captains: James Calvert, William McAdam Eccles, Herbert Morley Fletcher, Robert Cozens Bailey, John Hannah Drysdale, Louis Bathe Rawling, Percival Horton-Smith-Hartley, M.V.O., and George Ernest Gask. 5th Northern General Hospital: The undermentioned to be officers whose services will be available on mobilisation (dated Sept. 30th, 1908):—To be Lieutenant-Colonels: Frank Montague Pope, George Cooper Franklin, Reginald Pratt, and Claude Douglas. To be Majors: Astley Vavasour Clarke, Robert Sevestre, Thomas Villiers Crosby, John Thomas Horron Davies, Henry John Blakesley, Cecil Edward Marriott, John Stretton Sloane, and James Duncan Slight. To be Captains: Robert Stewart, Joseph Edward Waite, Felix Bolton Carter, Ernest Lewis Lilley, Richard Milbourne West, Robert Robertson Young, James Williamson Patrick, Edgar Vaughan Phillips, Sidney Frederick Smith, Ralph Michell, Leonard Erasmus Ellis, Frederick William Bennett, Robert Wallace Wesley Henry, Louis Kenneth Harrison, Wilfred Ernest Gibbons, Robert Hilton Fagge, Robert Basil Stamford, and William Moffat Holmes.

3rd Scottish General Hospital: The undermentioned to be officers whose services will be available on mobilisation (dated July 3rd, 1908:—To be Lieutenant-Colonels: Sir Hector Clare Cameron, Samson Gemmell, Ralph Stockman, and Robert Muir. To be Majors: Thomas Kennedy Dalziel, Henry Rutherfurd, James Henderson Nicoll, Walter King Hunter, John Marshall Cowan, James Walker Downie, Andrew Maitland Ramsay, and Duncan Macartney. To be Captains: William McLennan, James Laurie, Robert Barclay Ness, John McCubbin Johnston, James Carslaw, John Towart, John Morton, Alfred Alexander Young, William Walls Christie, Alexander MacLennan, Ernest George Fortune, James Campbell McClure, Robert Fullarton, John Gilchrist, Alexander Henry Edwards, Mathew Logan Taylor, John Gracie, Leonard Findlay, Charles Campbell Cuthbert, and Archibald Wilson Harrington.

4th Scottish General Hospital: the undermentioned to be officers whose services will be available on mobilisation (dated July 3rd, 1908):—To be Lieutenant-Colonels: Alexander Napier, James Crawford Renton, John Barlow, and George Stevenson Middleton. To be Majors: Robert Henry Parry, James Hogarth Pringle, Thomas Kirkpatrick Monro, James Grant Andrew, John Binnie McKenzie Anderson, Andrew Freeland Fergus, James Kerr Love, and David Couper. To be Captains: James Hamilton, Andrew Nicholson McGregor, Adam Brown Kelly, Andrew Stewart Tindal, Douglas Wills Russell, David Lamb, James Maclean, George Burnside Buchanan, Hugh Walker, Farquhar Macrae, Edward Mackay, James Weir, John Allan Cragie Macewan, James Donald Holmes, John Henderson, James Robert Chalmers, Alexander Fraser, David Fyfe, John Stoddart Barr, and Joseph Goodwin Tomkinson.

1st Southern General Hospital: the undermentioned to be officers whose services will be available on mobilisation (dated July 3rd, 1908):—To be Lieutenant-Colonels: Robert Saundby, Harry Gilbert Barling, Arthur Foxwell, and Frank Marsh. To be Majors: Robert Michael Simon, William Frederick Haslam, Otto Jackson Kauffman, James Thomas Jackman Morrison, Thomas Sydney Short, Harry Eales, John Douglas Stanley, and Charles Albert Leedham-Green. To be Captains: James William Russell, George Heaton, Joseph George Emanuel, William Billington, Arthur Stanley Barnes, Albert Lucas, Leonard George Joseph Mackey, Leonard Parker Gamgee, William Henry Wynn, Frederick Victor Milward, Frank Barnes, James Martin Young, and Walter James Clarke.

2nd Southern General Hospital: The undermentioned to be officers whose services will be available on mobilisation (dated Sept. 30th, 1908):—To be Lieutenant-Colonels: Robert Shingleton Smith; Edmund Comer Board, John Michell Clarke, and George Munro Smith. To be Majors: Arthur Bancks Prowse, James Swain, George Parker, Charles Alexander Morton, Patrick Watson Williams, Robert Guthrie Poole Lansdown, Cyril Hutchinson Walker, and William Robert Ackland. To be Captains: Francis Henry Edgeworth, John Lacy Firth, John Odery Symes, Thomas Carwardine, James Taylor, Henry Greville Kyle, Carey Franklin Coombs, Harold Frederick Mole, Edward Cecil Williams, Ernest William Hey Groves, John Matthew Fortescue-Brickdale, Edward Hugh Edwards Stack, John Freeman, John Dacre, Joseph John Scammell Lucas, Herbert Elwin Harris, William Cotton, Hedley Hill, and William Stuart Vernon Stock.

5th Southern General Hospital: Surgeon-Major Bonner Harris Mumby from the 3rd (Duke of Connaught's Own) Volunteer Battalion, the Hampshire Regiment, to be Major with precedence as in the Volunteer Force (dated April 1st, 1908).

2nd Western General Hospital: John Kyffin (late Surgeon-Captain, 1st Hampshire Royal Engineers (Volunteers)) to be Captain (dated June 25th, 1908); George Arthur Wright to be Lieutenant-Colonel (dated July 2nd, 1908); Captain and Honorary Major William Thorburn (late 2nd Volunteer Battalion, The Manchester Regiment) from the Retired List, to be Major (dated July 2nd, 1908). The undermentioned to be officers whose services will be available on mobilisation (dated July 2nd, 1908):—To be Lieutenant-Colonels: Graham Steell, Frederick Armitage Southam, Abraham Matthewson Edge, and Alfred Harry Young. To be Majors: Edmund Taylor Milner, Judson Sykes Bury, James Niven, John Edward Platt, Alexander Hill Griffith, Ernest Septimus Reynolds, William Milligan, and Robert Briggs Wild. To be Captains: Alexander Wilson, James Lorrain Smith, Arthur Henry Burgess, Henry Richmond Hutton, John Howson Ray, Richard Thomas Williamson, Evelyn Davison Telford, Ernest Nicholson Cunliffe, Philip Roscoe Wrigley, Charles Herbert Melland, William James Storey Bythell, Frederick Craven Moore, Richard Walter Marsden, Garnett Wright, George Edward Loveday, Albert Ramsbottom, John Wharton, Arthur Sellars, and William Arthur Hooton.

VOLUNTEER CORPS

Royal Garrison Artillery (Volunteers).—1st Aberdeenshire: Surgeon-Captain William A. Macnaughton resigns his commission (dated March 31st, 1908). 1st Banff: Surgeon-Lieutenant-Colonel William Fergusson is granted the honorary rank of Surgeon-Colonel (dated March 30th, 1908). Second Lieutenant Alfred L. Smith resigns his commission (dated March 31st, 1908). Surgeon-Lieutenant-Colonel and Honorary Surgeon-Colonel William Fergusson resigns his commission, with permission to retain his rank and to wear the prescribed uniform (dated March 31st, 1908). 1st Fifeshire: Surgeon-Lieutenant William E. Henderson resigns his commission (dated wider field of facts than enter into a useful or even legitimate mental equipment for the nurse must be irresistible to many young women of retentive memory and quick intellect; and the encouragement which their consequent examination successes bring them may well give them enough assurance to "put the doctor right" to their patient on some matter in which his treatment is founded upon a knowledge of those Institutes of Medicine of which they have the baldest and often merely parrot-like acquaintance. Doubtless many nurses with the requisite opportunities for a proper and statutory training would make admirable medical practitioners, but if their profession is to be nursing and not medicine we regard the present movement to give them a sort of bastard medical education to be unfortunate as tending to minimise the very important duties of nursing pure and simple. It is fair to say, however, that a number of text-books are published for nurses which have a perfectly legitimate function.

Of the four volumes before us that on midwifery has a special reason for its existence in that it is intended for the instruction of a legally recognised subordinate class of practitioners of midwifery as well as for nurses who act under constant medical instruction. Midwifery, too, is a subject which, even in its most elementary study, presents problems such as the mechanism of labour that can be greatly elucidated by an intelligently written text-book, and such a one is Dr. Jellett's, the success of which has been proclaimed by the issue of this third edition. Dr. Jellett is careful to define in his preface the limitation of the nurse's sphere of action. His claim to have simplified the book in this edition is justified and there is now no need to repeat the criticism which we were obliged to make upon its first appearance in the present guise. The scope of the work has been indicated in our columns previously. The present edition contains the rules of the Central Midwives Board for the regulation of midwives' practice and a glossary of terms which should be of service for nurses. We note that Dr. Jellett, in the preface, disclaims any connexion between this work and a book of similar aim written by a former Rotunda colleague.—Dr. Hellier addresses his manual on *Infancy and Infant Rearing* to an even wider audience, to wit, firstly, pupil midwives; secondly, health lecturers; and thirdly, students and practitioners. It will be seen that he has set himself a difficult task, for much that would be useful instruction to the last class would be entirely unnecessary for the needs of the two others. The book, however, contains little that could not be learnt with advantage by an intelligent midwife or "health-visitor," and we should imagine that its appeal to medical students was an afterthought of the author; if this were the case the afterthought was justified, for there are many hints in it concerning the normal progress of childhood a knowledge of which will redound to the credit of young practitioners. The important sections on feeding are done carefully and not too elaborately, and Dr. Hellier's pages contain certain shrewd observations which lift it above the level of many books about babies. The sections on infants' diseases are quite insufficient for the student's needs, which is as well, considering that they are addressed to others to whom fuller instruction might be dangerous.

The other two volumes hail from America. Dr. Langfeld's book on *Infectious and Parasitic Diseases* is another volume which though "primarily intended for nurses" has been extended to meet the requirements of medical students. This book is of a class that seems to us quite unsuited for the instruction of nurses, for we regard the author's statement that "the trained nurse's position as medical assistant to the doctor and as a sanitarian has developed into one of such extraordinary importance" to be an overstatement. We consider the nurse's duties as a nurse to be of paramount importance. No nurse requires instruction concerning antibodies or on the methods of making cultures and blood films. The volume, which is nicely printed, affords a useful little introductory manual to parasitology for medical students; its chief claim to utility and originality is in its etiological consideration of infective disorders. The chapter on animal parasites is well written. If a future edition should be called for Dr. Langfeld would do well to amplify it and to address it to medical students and practitioners alone, unless the conception of the nurse's functions differs widely in America from that held in this country.—Dr. Hoxie, in the preface to his *Practice of Medicine for Nurses*, the last of this batch, acknowledges that the nurse should neither diagnose nor prescribe. He states further that his book's part purpose is to help those who care for the sick in the home. We think that his work would be an unwise addition to recommend for a layman's bookshelf; there are quite enough home medicine books in circulation already. The author has hardly gauged correctly the educational needs of the nurse or he would not have included a bacteriological account of venereal disease. An elaborate classification of insanity, including Kraepelin's four varieties of dementia præcox, is also sadly beside the mark. The book contains some excellent pictures, but certain of them, notably that of a case of pathological obesity opposite p. 134, are quite unnecessary. Much, however, can be said on the other side. Such chapters as those on typhoid fever, pneumonia, and acute rheumatism are excellently done from the point of view of nursing, more especially the second of these. A chapter with the quaint heading "Two Popular Disorders, Catarrh and Asthma," contains a useful explanation of the former loosely employed term. The chapter on surgical nursing is commendably short. Practice, and practice alone, makes for efficiency in that branch of work. The medical information in the book appears to be sound except for the remark that as long as a patient suffering from Addison's disease takes adrenalin extract "he gets on well," which is surely an over-optimistic statement. The book concludes with an elaborate list of abbreviations used in medicine. We trust that nowadays no nurse requires the knowledge of such mysteries, for her instructions should always be written in plain English. One specimen of the present collection is entirely new to us, and in any case would appear to be only of interest to the druggist's errand boy. It runs, "N. tr. s. num.—*Ne tradas sine nummo.* Do not deliver unless paid."

Detection of Common Food Adulterants. By EDWIN M. BRUCE. London: Archibald Constable and Co., Limited. 1907. Pp. 84. Price 5*s.* net.—The compilation of this book is the outcome of recent agitation of the pure food question throughout the United States. We have no doubt that the series of qualitative tests given will be useful to those who have not made an exhaustive study of analytical chemistry. To the practising analyst the book will be of little value. The tests described, so far as we have examined them, are trustworthy, but some of them might easily go wrong in inexperienced hands. To do the author justice, he refers the reader who may wish to go further into the subject to the admittedly standard works on food adulteration and analyses. There is no reference in the chapter on beverages to malt liquors or spirituous drinks.

Atlas of Typical Operations in Surgery. By Dr. Ph. BOCKENHEIMER and Dr. FRITZ FROHSE. Adapted English version by J. HOWELL EVANS, M.A., M.B., M.Ch. Oxon., F.R.C.S. Eng., Demonstrator of Operative Surgery at St. George's Hospital, London, &c. London and New York: Rebman, Limited. 1906. Plates lx. and pp. 250.—The book descriptions of operations are often hardly intelligible to urine in the early stages and the cardiac sounds were muffled, especially the aortic systolic. With treatment these advanced cases got relief, but death usually claimed them after their third relapse. The nerve changes were noticeable in the early stages by their absence.

The post-mortem examination revealed an abundance of yellowish subcutaneous fat, an increase of serous fluid in the serous cavities, more particularly the pleural and pericardial, and in the latter it was richly pigmented. The heart was dilated and flabby, and exhibited fatty degeneration to a marked degree and was loaded with fat, and milk patches were common on the front wall of the left ventricle. The endocardium was pale and fatty. The valves were normal and clots—pale and gelatinous—existed in the auricles. The blood was very fluid and dark and the sternal marrow was soft, oily, and sanguineous. The lungs were congested and the liver was enlarged, very friable, and exhibited chronic venous congestion and fatty changes; no waxy degeneration. Bile was increased and thickened and the gall-bladder walls hypertrophied, and in many cases flint-like facetted calculi were common. The stomach was dilated and there was a great deal of emphysematous fatty tissue around the kidneys; the capsule easily stripped off and on section they showed fatty changes and venous congestion; the Malpighian bodies were prominent, pointing to a condition of parenchymatous nephritis. The spleen was enlarged and fatty and covered all over with fatty peduncular growths, and it cut like cheese, was very dark purple as if severely congested, and the trabeculæ were very prominent and of a pale colour. The pancreas seemed normal.

From the above it will be seen that there are many points in common in beri-beri with scorbutus and post-anæsthetic poisoning or fatty acid intoxication arising from faulty glycogenesis and disordered tissue metabolism.

I am, Sir, yours faithfully,
JAMES MONTEITH, M.B., C.M. Edin.
Oldham, Sept. 25th, 1908.

THE PREVENTION OF TUBERCULOSIS (IRELAND) BILL.

To the Editor of THE LANCET.

SIR,—I have read the letter of Dr. J. C. McWalter in your issue of Sept. 19th, to which I take grave exception and on which I beg to join issue. Dr. McWalter says: "Knowing what I do of the Irish people I believe that the compulsory notification clauses will excite so much suspicion and dread as effectually to undo any good result heretofore obtained from the tuberculosis campaign." That is Dr. McWalter's opinion; but as it is a forecast of what he thinks will happen in the future to a movement which he fully recognises "has done much good," I do not feel bound to vie with him in the rôle of prophet of evil. "The evil which men do lives after them," but in this instance I hope that the good which has been admittedly done by Lady Aberdeen and those who have had the honour and the privilege of working with her in the anti-tuberculosis movement in Ireland will live and extend. Dr. McWalter says that the movement "has a source of weakness in not being controlled by those *in close touch* with the popular party." Is Dr. McWalter entitled to speak for the popular party? Is he *in close touch* with that party? Whom does he desire to place *in control* of the movement which he admits has accomplished so much good? I am of the popular party. So far as I know I am not quite out of touch with it. I know the feelings, the hopes, the fears, the aspirations, aye, even the prejudices of our people as well as Dr. McWalter. I have been north and south and east and west from no selfish or sordid motives. Like others in the movement, I have been willing to sacrifice time and ease and convenience to try and do something towards saving our perishing people. Dr. McWalter tells us of his success in dealing with public boards in Dublin, because they are satisfied that "he is acting unselfishly." "But," he adds, "members of such boards are prone to suspicion; and it is difficult to assure them that a practitioner is entirely unbiassed if he advocates a system *which will put half-crowns in his pocket*, whilst it impales for life the person notified." I protest most strongly against this unworthy and unwarrantable suggestion of Dr. McWalter. It strikes at the honesty and integrity of the members of our profession in Ireland and impugns the motives of those who are acting, as they believe, for the public good without hope of fee or reward. Their conduct is as unselfish and as free from taint of unworthy suspicion as Dr. McWalter's. The question is too urgent, the issue too grave, to be brushed aside in deference to prejudices or suspicions which, if they exist, are ill-founded and baseless, and which educated and enlightened public men like Dr. McWalter should endeavour to combat and overcome, not foment and foster.

I am, Sir, yours faithfully,
MICHAEL F. COX, M.D. R.U.I., F.R.C.P. Irel., M.R.I.A.,
Physician to St. Vincent's Hospital.
Dublin, Sept. 21st, 1908.

To the Editor of THE LANCET.

SIR,—I feel constrained much against my will to brea lance with Dr. McWalter over his attitude towards the at Bill. As a member of a sanitary authority he is no doub close touch with the prejudices of those who will be m largely affected and must be therefore fully aware h necessary it is not to do or say or write anything that w strengthen or accentuate those prejudices. The Bill has be framed by the Irish Local Government Board with t obvious desire to interfere as little as possible with the u fortunate subjects of the disease and only those provisio of the Infectious Disease (Prevention) Acts which a absolutely necessary to safeguard both the patients and t public are made applicable to tuberculosis. Whilst th Scottish Local Government Board unhesitatingly expresse its opinion that tuberculosis as an infectious disease cou be added to the list of notifiable diseases under the 1889 Ac and urged sanitary authorities to make applications to the for that purpose, the English and Irish boards absolutel refused to yield to the supplications of certain of thei sanitary authorities on the ground that, if such were done all the pains and penalties that attend the notification o such diseases as scarlatina, small-pox, and diphtheria woul be exercisable against notified cases of tuberculosis. In consequence of the enormous amount of public feeling that ha been aroused on this question and in response to the almos universal demand on the part of public representative bodie in Ireland, the Irish Local Government has introduced a Bill so framed as to make tuberculosis a notifiable disease and at the same time avoid even the appearance of harshness or official interference. In order to have a proper knowledge of the existence and prevalence of the disease which is essentially necessary if we are to cope with it successfully the first thing is to get information as to its whereabouts. And this can only be obtained by a system of notification, and under the system formulated in the Bill there is not the slightest excuse for anyone, much less one possessed of the legal acumen and mental calibre of Dr. McWalter, to suggest that there is the least probability of any person being treated as a leper or in any respect avoided either in his home or workshop. The bugbear about expense is also a mere shadow: outside the large cities the half-crowns that will gravitate to the pockets of the medical profession will be inconsiderable and will, I hope, in a few years reach vanishing point. When Dr. McWalter says the anti-tuberculosis movement in Ireland has an inherent source of weakness in not being largely controlled by those in close touch with the popular party I must confess I cannot understand what he means. No similar movement ever had such united and general support. It brought together men and women of all classes and creeds and all shades of politics. It collected on one platform the clergy of all denominations; professional men vied with each other in their efforts to acquire and dispense information, and, in fact, the whole country was alive with enthusiasm. However, Dr. McWalter thinks we should "go gently." We have been going gently for the past 30 years and what has been the result? We are in sanitary matters at least 30 years behind either England or Scotland. The English Public Health Act dates from 1875, the Irish Act from 1878; both are framed on exactly the same lines, and in addition the Irish Act established a complete system of medical officers of health by making all the dispensary doctors health officers for their respective districts. Instead of carrying out the intentions of the Act and calling upon the sanitary authorities to combine and appoint medical superintendent officers of health the then Local Government Board adopted the very construction and less expensive to work than the county asylums as they are at present. 2. To settle suitable patients in family colonies or in cottages and small buildings in connexion with some central organisation formed for the care of mentally defective persons. The Royal Commission has examined the system provided at Dun-sur-Auron in France and that obtaining at Gheel near Antwerp, where accommodation is provided for patients in the neighbourhood of an asylum, and it has come to the conclusion that a system of family care or guardianship adopted with well-defined sanitary and medical safeguards is well worthy of consideration and might with advantage be adopted in this country. 3. To board out the mentally feeble of this class as is done in the "family guardianship" system which obtains in Scotland. It appears that in that country this method, though of recent establishment, works smoothly and satisfactorily and has been adopted in certain parts as a form of industry. 4. To place patients in large farm colonies on the lines of certain colonies established in the United States and in Canada. Quite extraordinary results appear to be produced in these farm colonies by men whose lives are devoted to the care of the mentally defective, results which may throw light even on the methods of education of normal scholars in public elementary schools. The last alternative whereby the patients would be returned to the workhouses is rejected summarily and it is laid down that the workhouses should cease to be asylums for lunatics. It is interesting while considering the cost of these various schemes to quote the evidence of Mr. Clare, the clerk to the Lancashire Asylums Board: "I should not like to commit myself to any figures, because one sees the variation in the cost of asylums recently built; there is only one thing that seems invariable—namely, an increase in cost as time goes on, largely owing, of course, to the increased cost of wages and material, and partly to carrying out the latest scientific ideas, or philanthropic ideas, for dealing with pauper lunatics, without any evidence really to show that the increased expenditure has benefited lunacy; in fact, as far as I can see, all the expenditure during the last 20 years on lunacy has not been any benefit to lunatics. I will not say it has done any harm, but there has been no substantial benefit derived." Even if this is only in part true, it is plain that some method of dealing with the pauper lunatic without incurring a large initial expenditure is well worth consideration.

To house the hopelessly insane in such a way that they may be efficiently and economically looked after forms an important part of the problem set before the Commission, but another equally important part is that which is concerned with persons commencing to be mentally ill. It has been widely recognised as an undoubted hardship that the patient who is at the commencement of his illness should forthwith be certified as a lunatic. The consequences to the individual's career are often disastrous as a direct result of this procedure and a stigma forthwith attaches to him which may render him unemployable in his occupation. It is to this unfortunate state of things that we must to a large extent attribute the too frequent postponement of treatment, so important in an early stage, to the day when the patient is hopelessly ill and his chances of recovery are enormously reduced. Certain methods of meeting the difficulty were suggested to the Commission. The first is the establishment of "observation" or "reception" houses or wards where a patient who is suffering from any form of mental disorder may be admitted freely and at once with a view to his being treated at an early stage of his disorder and without certification. We have before commented in these columns on the excellent results obtained in certain institutions of this character in Scotland and we believe the possible establishment of similar institutions in this country to be the fondest hope of those practising psychological medicine. The observation wards of the Eastern District Hospital of Glasgow were opened in June, 1904, and since then large numbers of patients suffering from various kinds of mental disorder have been treated there. Of these no less than 61 per cent. were discharged either cured or relieved. It is no wonder that there is a general consensus of opinion in favour of the utility of these wards. The change, as the Commission points out, marks a further step towards the substitution of the hospital for the asylum. The procedure for entering the wards is simple and merely involves the production of a medical certificate to the effect that it is desirable that the patient should be observed and treated. It is not a certificate of detention. The method permits of a more scientific handling of the problems of mental defect than is at present possible and allows of the disease being combated at the earliest possible moment. Dr. F. S. Toogood, the medical officer of the Lewisham Infirmary, brought before the Commission an interesting account of a similar method of dealing with cases of mental illness adopted by him at Lewisham. The relieving officer conveys the patient to the workhouse or to the infirmary, either upon his own authority or upon the direction of a justice of the peace after a medical examination, and the patient is there detained until fit to be discharged or sufficiently confirmed in his illness to be sent to the county asylum. In Dr. Toogood's words, "The great majority of cases treated in these wards, although temporarily insane and requiring control and observation, are not asylum cases." The disease is dealt with apart from the "stigma of lunacy," for "friends do not object to the detention in infirmaries or workhouses but they have a very keen horror of an asylum." The Royal Commission reaches the conclusion that by arrangement between the Board of Control and the local authority there should be reception wards or houses wherever they may be necessary and that whatever legal provision is required for their establishment should be made without delay. It is not thought necessary that large and expensive buildings should be erected but that separate wards in workhouses or in general hospitals might be used under contract. The report points out the special advantages of these wards for the clinical study of mental disease and the probability that the hospitals, especially those to which medical schools were attached, would be glad to provide them on their own premises.

The report is favourable to a procedure which is borrowed from Scotland and which is applicable as a temporary measure to "unconfirmed cases." The certifying medical attendant declares that his patient is afflicted with a certain disease and that with a view to his recovery it is desirable that he should be placed in such and such place for a temporary residence, the term not exceeding six months. It is not necessary to put in the certificate anything indicating that the illness is mental, but it is usual to put in some reference to mental or nervous disturbance. It is proposed that if this procedure is adopted in this country the Board of Control shall be required to undertake the registration, supervision, and inspection of all houses in which two or more mentally defective persons are maintained for private profit.

With regard to certification the most important recommendations of the Commission are, first, that the word "lunatic" should be replaced by "mentally defective person" and the word "pauper" eliminated; secondly, that the local committee may present a petition, as next friend, where it thinks that such a petition should be presented, either at the request of the friends or when the friends have failed to act; and thirdly, that the judicial authority may select a suitable institution or house or leave the selection to the committee in cases where the friends have failed to act.

The report, besides the chapters which we have attempted to summarise, contains others bearing upon the causation of mental defect, upon finance in connexion with the new schemes, upon epileptics, and finally, special chapters upon the conditions of the mentally defective in Scotland and Ireland. The whole report is replete with the most interesting and valuable information as well as with the reasoned conclusions of a body of men eminently fitted to grapple with the serious problems presented for their consideration. We earnestly hope that the report may not follow many of its forerunners to that limbo of forgetfulness where lie unused so much priceless information and knowledge bred of unique experience.

ST. MARY'S HOSPITAL MEDICAL SCHOOL (UNIVERSITY OF LONDON).—Award of entrance scholarships, 1908. Open scholarships in natural science: £145, B. W. Armstrong, Boston Grammar School; 75 guineas, F. P. Bennett, University College, Cardiff; 50 guineas, J. R. M. Whigham, Westminster City School; 50 guineas, F. C. Robbs, Clarence College, Gravesend. University scholarships: 60 guineas, A. W. Bourne, B.A., Downing College, Cambridge; 60 guineas, W. A. Berry, Queen's College, Belfast. Epsom College scholar: E. P. Langley.

know of none, as the work both of the Protection Society and of the Union includes not only defence against actions for alleged negligence but advice and assistance in all matters pertaining to the medical profession, illustrations of which can be found in the annual report of either society. If we were to confine our duties solely to cases of alleged negligence such as insurance companies may possibly undertake, a very large proportion of our assistance to the members would cease, to their great disadvantage. The scope of our work is far-reaching and would be impossible to other than purely medical professional organisations with many years' experience and with an expert staff.

I am, Sir, yours faithfully,
A. G. BATEMAN,
General Secretary.
Medical Defence Union, 4, Trafalgar-square,
London, W.C., Sept. 26th, 1908.

To the Editor of THE LANCET.

SIR,—In reply to "Practitioner's" inquiry in your current issue there are two well-known medical defence societies, one with offices at 4, Trafalgar-square, W.C., and the other, The London and Counties Medical Protection Society, of 31, Craven-street, Strand. Both of these societies undertake to defend members in actions for malpraxis but contribute nothing towards damages arising from such actions in cases of adverse verdicts. *Re* "Practitioner's" second query, the policy he requires can be obtained from Messrs. Aked and Aked, 43, Warwick-street, S.W., who are, I believe, the sole agents.

I am, Sir, yours faithfully,
VINCENT P. NORMAN, L.M.S.S.A. (Lond.).
Stepney Green, E., Sept. 29th, 1908.

AMYL NITRITE IN UTERINE HÆMORRHAGE.

To the Editor of THE LANCET.

SIR,—It would be most useful to know if in uterine hæmorrhage nitroglycerine could be given by the mouth instead of inhaling amyl nitrite, as nitroglycerine is said to be more persistent and slower in its action.

I am, Sir, yours faithfully,
G. P.

COLLES'S FRACTURE.

To the Editor of THE LANCET.

SIR,—To the *Journal of the American Medical Association* some weeks ago Dr. L. W. Ely of New York contributed a paper on Colles's fracture. It is important to bear in mind that Colles described a very definite fracture with a definite displacement and therefore the title Colles's fracture should be limited to this variety or it should be given up entirely. Dr. Ely's paper is of great interest in that it endeavours to explain the mode of production of the fracture from the structure of the bone. He appears to consider that fracture of the styloid process of the ulna is an essential accompaniment, but skiagrams, which have taught us so much about Colles's fracture, tell us that the lesion of the ulna, though frequent, is not essential. Dr. Ely also condemns strongly the idea that the impaction should not be interfered with and I agree with him, but surely nowadays no one advances the opinion which he attacks.

It may be interesting to recall the exact circumstances in which Colles's fracture received the name which for nearly a century has been given to a certain form of fracture in the neighbourhood of the lower end of the radius. Dr. A. Colles, who was one of the professors of anatomy and surgery in the Royal College of Surgeons in Ireland, wrote a short article which appeared in the April number of the *Edinburgh Medical and Surgical Journal* of the year 1814, entitled "On the Fracture of the Carpal Extremity of the Radius," and in it is given for the first time a very clear and exact account of that fracture which is still called "Colles's fracture." Colles describes the fracture as occurring about an inch and a half above the carpal extremity of the radius, and he mentions the displacement backwards of the carpus, combined with the tilting backwards of the lower extremity of the radius. He describes the method of reduction and the great tendency to recurrence which exists. It may reasonably be asked, "Was not this fracture recognised earlier?" Doubtless it was, but for the most part it is probable that the cases of this form of fracture were diagnosed as dislocations of the wrist or perhaps as examples of Dessault's dislocation of the lower end of the radius.

I am, Sir, yours faithfully,
F.R.C.S.
Sept. 25th, 1908.

THE PRESENT CONDITION OF PHARMACY.

To the Editor of THE LANCET.

SIR,—In reading your leading article published last week under the above heading there came prominently to my mind the contrast between the relationships existing in two seaside towns in the West of England between their medical practitioners and their pharmacists. In one it is (or was two years back) a state of antagonism, in the other a state of coöperation. In illustration of the former case I need only quote the grievance of a prominent pharmaceutical chemist who complained to me that a certain practitioner not only dispensed his own medicines but that he undersold him by supplying elastic bandages to his patients at a bare margin of profit. But the object of this letter is to heal and not to fret a sore, so I will pass to the practice obtaining in the other town. In that place an arrangement has been made between several medical men who formerly "did their own dispensing" and a pharmaceutical chemist, by which the former are relieved of all that irksome business, whilst the latter comes by much more of his legitimate custom than he could hope to under the old system. The arrangement in question is based on the well-known fact that patients who pay 3*s.* 6*d.* or 5*s.* for advice do not like to have to pay for their medicine too. The medical man writes his prescription which the patient takes to the chemist in question, the latter makes it up, gives him the medicine, and charges the medical man from 5*d.* to 6*d.* a bottle for it. This simply means that his fee for consultation, including medicine, is 6*d.* more than for advice without medicine. The great point is that the patient only pays one charge instead of two; incidentally, he probably gets more elegant pharmacy than in the days when the medical man dispensed his own medicines, the evening labours of the practitioner are greatly lightened, whilst the chemist earns far more in sixpences than he used to earn in eighteenpences. The whole thing is perfectly fair and aboveboard. There is no question of "secret commissions," for the system is fully explained to the patients. The practice may be general in small towns, for which it is specially suitable, but I am constrained to mention it by the memory of that other place where medicine and her chief handmaiden are (or were) at such unhappy loggerheads.

I am, Sir, yours faithfully,
LIVE AND LET LIVE.
Sept. 29th, 1908.

THE SECOND CONGRESS OF THE INTERNATIONAL SOCIETY OF SURGERY AT BRUSSELS.

(FROM OUR SPECIAL CORRESPONDENTS.)

(*Continued from p. 975.*)

THREE years ago the International Society of Surgery decided to discuss in 1908 Cancer, the Surgery of the Liver, Anæsthesia, and Hernia.

Cancer.

The subject of cancer was taken first and a series of formal reports was in the hands of the members at the time of the meeting. The first of these reports was by Dr. ROSWELL PARK (Buffalo) who maintained that cancer was essentially infective and that the disease must therefore be treated on the same lines as a filth disease. Cremation should supersede earth burial after death from cancer. All soiled dressings and discharges should be destroyed by fire, whilst rooms and even houses inhabited by cancer patients should be most thoroughly disinfected, both during illness and after death. As regards the individual Dr. Roswell Park held cancer to be essentially a local infection at first, generalisation taking place quickly, though the rate of spreading varied wonderfully in different individuals and with different forms of cancer. The treatment, therefore, was bound up with early to look like promising endless developments but there is reason to suppose that they, too, as far as medicine is concerned, have reached a sterile perfection. The *microscope is perfected up to a point* which mechanicians think cannot be improved upon, so that those ultimate elements of physiology which depend upon the observation of minute structure are known to us." He proceeds to say that he will not labour the point by applying it to botany or to chemistry where he perceives that the finality of our work is by no means clear, but he suggests *that the result of a feeling that not much more is* to be got from minute observation with the tools at the disposal of the medical man has been the shunting of the brightest intellects and most inventive work into more imaginative channels. "There are no men," he says, "who guess so brilliantly as men of science, so that science in that respect has attained the dignity of theology. ...... *But the human intellect,* especially if it is scientific, cannot, I imagine, like an actor, go on repeating or feigning the same emotion. ...... The tree of knowledge is an evergreen, and in science no more than in arts is there any decay."

Such suggestive criticism of the position of modern medicine is welcome, whether we agree with it *in toto* or find in the propositions of the lecturer, tinged as they are with irony and expressed in frequent paradox, material for dissent. Mr. Ross is careful to warn us against the danger of according exaggerated praise to the unworthy in the desire to acclaim merit, and he does so in terms which may be quoted as containing a suggestion of the aims to which modern medicine should be directed. "I do not ask you," he says, "to adopt the habit against which MATTHEW ARNOLD directed one of his witty essays, the habit of expressing a too unctuous satisfaction with the age and time in which we are living. There are problems of poverty, injustice, disease, and unhappiness which should make the most prosperous and most selfish of us chafe; but I do urge that we should not suspect the art and literature of our time, the intellectual manifestations of our age, whether scientific or literary." In the practical application of medical science the resolution of some of those problems may be found; and the present time is the opportunity of the man of science and of those in sympathy with him to make their mark and to prove that this is an age not of decay but of progress; while it is in resistance to such progress that the carping spirit which claims to detect decay in all modern development will most openly show itself. Intelligent appreciation must ever be based upon knowledge of the thing criticised, upon some sympathetic insight into the aims and motives of the worker, and must be guided resolutely in accordance with the principles of truth. When the hymner exclaimed, "Change and decay in all around I see," he was in a frankly despondent mood. Those who feel like him may take heart from the fact that change and decay are not synonymous terms. Cessation of effort may occur in one place, but if it is replaced by activity of the finest sort in another the net result will be progress and not decay. And this is Mr. Ross's message, and we congratulate him upon the humour and knowledge with which it is delivered.

Report on the General Prisons Board for Ireland, 1907-08.

WITHIN the last few days we have received from the Irish Stationery Office two Blue-books which are of more than ordinary importance. To the first of these—the report of the Registrar-General of Ireland for last year—we devoted an article in THE LANCET of Sept. 26th (p. 946). The second Blue-book embodies the report of the Commissioners of the General Prisons Board for Ireland; and inasmuch as it contains matter of considerable medical interest we proceed to notice it briefly on the present occasion.

Passing over the merely statistical portion of the document as of mainly local interest, we observe that the Commissioners devote particular attention to reformatory work among the juvenile offenders of Ireland. The "Borstal" system is in operation at several of the prisons in Ireland, and respecting the good effects of this system the Commissioners report in terms of high appreciation. From a full description of the system in the report we summarise the following particulars. Under the Borstal system all boys, immediately on committal, are strictly isolated from contact with the ordinary adult prisoners. They are fed on generous diet and special attention is paid to every detail of their health and education. They are employed during specified hours in learning useful trades and in times of recreation they are carefully looked after by the chaplains and other officials. On their discharge from prison the "Borstal" boys invariably appear improved in physique and they are certainly better mannered than on their committal. In fact, in the words of the Commissioners, "While undergoing their term of punishment every inducement is held out to them to keep away from vicious habits in future and the results are most encouraging." The principal drawback to the success of the "Borstal" system appears to be the shortness of the sentences inflicted on many of the "juvenile-adults," which in the case of a large proportion of the lads sent to Clonmel last year were for the minimum period of nine months. This drawback, however, will to some extent be remedied in the event of the passing of the Prevention of Crime Bill now before Parliament, one year being the minimum period of detention proposed by that measure in Borstal institutions. The Prevention of Crime Bill is intended to deal with two classes of offenders who occupy the extremes of the present prison population—namely, the young offender and the habitual criminal. The Bill provides in both these classes for the compulsory detention of the offender—in the first class with a view to his reformation and reclamation; and in the second class, for the protection of the public, the mode of incarceration in the latter case being known as "preventive detention."

The health of the prisoners throughout Ireland is stated in the report to have been very good. Commenting on the fact that of the three divisions of the United Kingdom Ireland has now the largest proportion of tuberculosis amongst its general population, the Commissioners remark that the amount of this disease in the Irish prisons is very small, as compared either with prisons in other countries or with the general population of Ireland, although so many prisoners

Dr. S. B. Atkinson, since that date her services have ceased. A large baby show which has been held recently in the centre of Stepney is regarded as affording a good opportunity for starting a motherhood bureau or some centre whence information on all matters of infantile hygiene could be readily obtained. It will be a valuable thing for the community if this expectation is realised; at present the poor nursing mother of Stepney gets none of the assistance which might be so valuable to her.

I now went on to Rotherhithe, and nowhere can conditions be found more favourable for studying the problem of the rearing of poor children. Rotherhithe, which once was prosperous, has long since fallen from its high estate. Much of its trade has departed, though its position on the bank of the Thames still necessitates the employment of a considerable number of dock workers. Unfortunately, the supply largely exceeds the demand, and many men can only obtain casual employment. Their wives and families are in a condition of continual poverty. The brunt of the physical suffering, the natural hunger, is borne, of course, by the women and children, and the women suffer even more severely than the children because of their ready self-sacrifice of themselves. It is the ordinary sequence of events that a man obtains a few days' employment, having had no work for a week or two. When he procures this casual job his wife is able to obtain credit and food is secured, of which the man must consume by far the largest portion or he cannot do his work. The woman in most instances stints herself to a bare subsistence for the sake of the children. The woman exists upon the minimum of food that will support existence, and if she happens to be pregnant it can be conceived that the chances for the offspring are very black. It is in a locality like Rotherhithe that expectant and nursing mothers of the poorer class especially need nourishment, and none of the dread lest pauperisation by charity should lead to loss of self-respect need enter into the question. Women who starve themselves for their children do not lose moral fibre because they are helped to feed those children, and a too severe attitude of organised charity would be out of place in Rotherhithe. The Bermondsey Settlement, the headquarters of which are at St. George's House, Bermondsey, but which has its women's house and its women and children's house in Rotherhithe, has attempted to grapple with some of the difficulties which young mothers meet with there. Miss Simmons is at the head of the women's work. At St. George's House, Bermondsey, babies' breakfasts are given through the winter up to May and bread and milk is given to children too young to come under the school feeding system and too troublesome to be cared for at the same time as the other children. In connexion with the Settlement what is known as a Babies' Institute has been established. A good-sized house, known as Beatrice House, has been hired in Rotherhithe in which on certain days of the week mothers' meetings are held and advice is given by competent women in regard to the bringing up of young children. At this house on one day of the week infants are inspected and weighed. A nurse and two ladies connected with the Settlement supervise these proceedings and a medical man attends at intervals to inspect the infants medically, to give advice, and to recommend treatment when necessary. Pamphlets and leaflets containing instructions as to the proper mode of rearing infants are distributed, setting forth the aim of the institute and the principles of hygiene to be followed in the bringing up of infants. To help mothers, especially young mothers, to prepare for the birth of children, and to take efficient care of themselves and the baby, both before it comes into the world and for the first year of its life, a provident maternity club is to be established, and it is intended, if sufficient support can be obtained, to adopt to some extent the system of feeding expectant and nursing mothers. This is done already on a very small scale, and all who know the conditions hope that the movement may spread in this poverty-stricken neighbourhood. I was present at one of the mothers' meetings, at which babies were inspected and weighed. Both mothers and infants as a lot were anæmic and ill-nourished. The women took, as usual, the keenest interest in the weighing of the babies and the spirit of emulation which is invariably aroused in these circumstances soon began to prevail among them. The increase of weight of their respective offspring became a matter of personal dignity to themselves. Also, they seemed to pay great and grateful attention to the advice given to them.

The obviously forlorn and ill-fed appearance of many of the women in Rotherhithe made me wish to see them in their homes. With the assistance of a Poor-law district medical officer for Rotherhithe, Dr. B. A. Richmond, who has lived in the neighbourhood for some time and who knows the houses of the poor well, I was able to witness the life led by the mother at home. The houses, with the exception of the model dwellings, are old, small, ill-lighted, and possess many sanitary defects. The first house into which my conductor took me was situated in a narrow side street and consisted on the ground floor of a low-ceilinged, badly lighted room in front, not more than 12 feet square, opening into which was another room, windowless and just large enough to contain a truckle bed in which a girl slept. There were two very small rooms upstairs in which the remainder of the family, comprising man and wife and three children, slept. The food of the family was kept, in default of other accommodation, in a small cupboard in the dirty and stuffy front room, and the provision for cooking it was a gas stove at the end of the narrow entrance passage and in close proximity to the water-closet. The street was ill-paved and narrow, and the other houses, which I daresay are among the oldest in Rotherhithe, are much like the one described, though a few have outside yards, allowing a little more space for cooking and sanitary arrangements. In an adjoining street was a house to which I was conducted containing two rooms on the ground floor and two on the upper floor. In the front room the greater part was occupied by a large wooden bedstead, for, of course, the more numerous the family the larger the bedstead, while, with less obvious connexion, the larger the bedstead the smaller the room. In bed here was a woman who had been confined a few days before, making her eighth child, but in this tiny house two nearly full-grown girl lodgers also received accommodation, so that of the two small rooms upstairs one was occupied by six girls and the other by three boys. There was an outside yard in which was the closet and in another part of the yard a cupboard in which the food was kept. The people of this house were not particularly poor and the overcrowding, which constituted a menace to their health, was not really necessitated by their circumstances. The rent of the house was 8*s.* 6*d.* per week. The next houses which I visited were situated near the river and were more distinctly reminiscent of Rotherhithe as a riparian suburb. The first house was large with a long passage running its full length and leading into a yard. It contained seven rooms, most of them panelled, all of them inconvenient and ill-lighted, and two of them which were used as bedrooms with no outside light whatever. The rent of this house was 11*s.* 6*d.* per week and it was filled with lodgers. The food was kept in a cupboard in the yard. A second house was of a similar description, with dark short stairways leading from room to room. But here also there was an outside yard with storeroom for food and a closet. This house had as inmates a man, wife, and family of four, and several lodgers. Another house which had been undoubtedly in days past the mansion of a family of some position and which was now used as a lodging-house, swarmed with children and was grimy beyond description. In the last house which I shall describe, situated in a narrow lane not far from the river, a woman under 30 had been confined recently with her sixth child, the other five children being alive, the general conditions were even worse. The house was small and disgustingly filthy. In a diminutive front room, with fire burning and window tightly closed and atmosphere absolutely foul, containing a very large bedstead, sat the woman with her last baby in her arms, and on the bed were two half-naked youngsters. The woman had no one to assist her, and in order to attend, after a fashion, to her large young family, was compelled not only to get up before she should rightly have left her bed but to do what cooking her means allowed her to have. Probably the food was kept under her bed, for this appears to be no very uncommon incident where receptacles are practically absent, and she could not have placed it far from her because of her condition. I inspected many other houses, but I think I have said sufficient to show that in Rotherhithe there is ample scope for the employment of many health visitors. I am sure that much, very much, could be done, nocturnal pains, periostitis, and necrosis of the femur, tibia, clavicle, and bones of the forearms; and the joints become distended with fluid and sometimes ankylosed. Gummatous ulceration destroys the eyelids, nose, and ears, producing innumerable varieties of mutilation which may be witnessed every day; and the amount of inherited syphilis is enormous. In every part of the country there are constantly met boys and girls between eight and ten years of age who are thus affected, frequently with osteo-arthritis of both knees. Caries of the bones of the face and of the base of the skull is common, and also blindness due to interstitial keratitis. With regard to the effect on childbirth and infant mortality Colonel LAMBKIN quotes from Dr. C. A. COOK, C.M.S., the calculation that 75 per cent. of the pregnancies of the Uganda women end in abortion or miscarriage, premature labour or stillbirth, or in the death of the infant during the first week after delivery. Parasyphilitic affections are not very common and Colonel LAMBKIN assumes that the disease has not existed in the country for a sufficient length of time to produce any abundance of them. Still, a certain number of tabetic cases have fallen under his observation and "quite a number" of young men with syphilitic histories who were suffering from complete loss of sexual power.

With regard to the causes of the epidemic—for so, indeed, it may be called—Colonel LAMBKIN gives the first place to the supersession by Christianity of the tribal laws and customs which formerly prevailed, under which the liberties of women were greatly restricted and unchastity was severely punished. Christian teachers have brought about the abandonment of polygamy and of a control over female liberty which was formerly exerted, and under which immorality and promiscuous intercourse did not exist. Corresponding with the time of the outbreak of syphilis, the chiefs of the Baganda tribe, the majority of whom had become Christians, decided to remove all such restrictions, as being contrary to Christian teaching, and to set the women free. This was done, and the women were left at liberty to roam about and to do as they liked, with the result of establishing a system of promiscuous sexual intercourse and immorality. The freedom enjoyed by women in civilised countries has gradually been won by them as one of the results of centuries of civilisation, during which they have been educated; and women whose female ancestors had for countless generations been kept under surveillance were not fit to be treated in a similar manner. They were, in effect, merely female animals with strong passions, to whom unrestricted opportunities for gratifying these passions were suddenly afforded. The opinion thus stated is confirmed, it is satisfactory to observe, by competent witnesses who are themselves Christian teachers; and Colonel LAMBKIN cites the testimony of the Rev. J. ROSCOE of the Church Missionary Society, Chief of the Theological College at Kampala, and that of the Very Rev. Père LAANE, Superior of the White Fathers at Entebbe, whose labours for the relief of the sufferers from sleeping sickness have lately called forth a warm eulogium from Mr. HESKETH BELL, the Governor of Uganda. As a second cause the abolition of the punishments formerly inflicted upon offenders against chastity is mentioned and is said to have encouraged the commission of such offences, and thus to have lent itself to the propagation of syphilis amongst the people. Colonel LAMBKIN concludes his paper by a sketch of an organisation which he has established, with the aid of the local chiefs, for the cure of persons suffering from syphilis, and under which treatment rooms will be opened in various localities, while a sufficient regularity of attendance on the part of the patients will be secured through the agency of these chiefs and of the control which they still exert over their people. Colonel LAMBKIN found a prevalent opinion among medical men in the Protectorate that the natives were bad subjects for the administration of mercury, but this view has not been sustained by his own experience and he advises its free administration under ordinary precautions. In conclusion, he believes that it is possible to count upon even more complete control over the patients in Uganda than in India, the influence of the chief over his people being remarkable and his word being law, and that hence there is every reason to think, without being too optimistic, that our chances of being able to deal successfully with syphilis in Uganda are at least as good as they were ten years ago in India. If we can bring about anything like the brilliant results achieved in that country we shall, he says, have much cause for congratulation.

"Ne quid nimis."

THE NOTIFICATION OF PULMONARY TUBERCULOSIS.

A COMPARATIVELY open secret was disclosed at the International Congress on Tuberculosis at Washington by Dr. A. Newsholme, principal medical officer of the Local Government Board. Dr. Newsholme, speaking on the authority of Mr. Burns, the President of the Local Government Board, made the expected announcement that the Board proposed to put upon Poor-law medical officers the duty of notifying, to all sanitary authorities who requested the information, all cases of pulmonary tuberculosis occurring among patients who are a charge to the parish. Such an order, to be of any use, will also make it compulsory upon the guardians and their staff to notify changes of address of parochial patients suffering from pulmonary tuberculosis, and no doubt the details of such notification will be arranged. It seems to us that a good deal of care will have to be exercised in this latter direction lest anything that looks like the unnecessary segregation of a class should lead to concealment of a certain number of exactly the kind of cases that ought to be under active treatment.

AN EXPERIMENT IN CONTRACT PRACTICE.

THE medical men in the town and suburbs of Bellinzona, who have been making what we should think a somewhat bold experiment in contract practice on extensive lines, have soon discovered to their cost what an inordinate amount of unnecessary trouble thoughtless people manage to give when they only have to pay a fixed sum—usually a very small one—per annum. An arrangement was made whereby the locality was divided into districts, the inhabitants paying a small rate to the local municipal authority, out of which the medical men received from £120 to there is someone present at the exhibition to take parties round and to explain. Thus an immense educational work is done.

There are now no less than 195 State or local associations for the prevention of tuberculosis. To show how quickly the movement has grown it suffices to consider the following few figures. At the commencement of 1905 there were only 24 associations for the prevention of tuberculosis throughout the whole of the United States and then 12 new ones were created. In 1906 25 new associations were started. In 1907 the doubling process continued, since in that year 49 new organisations sprang into existence. But the first seven months of the present year beat all former records by creating 85 new associations. The rapidity of the increase shows the popularity of the cause and the ability with which it has been advocated. As already remarked, the object is purely educational and one of the difficulties has been to check the over-zealous. Others seek to advertise themselves rather than to make themselves really useful, so that some associations have been formed which it was thought wiser not to recognise. The committee governing the National Association has been carefully selected from among eminent medical men and some laymen who have had great experience in such matters and are fully cognisant of the sort of difficulties likely to arise. Dr. Livingston Farrand, who has been very active in this organising work and who supplied me with much of this information, will give further details at Washington and the foreign members will be profitably interested in the practical information thus forthcoming. There is a book also about to appear, of which I have some proof sheets, containing a complete list, accompanied with some practical details, of every sanatorium and hospital in the whole of the United States specially intended for tuberculous patients. This will be a very useful publication.

RECENT OUTBREAKS OF PLAGUE IN THE NEAR EAST.

(BY THE BRITISH DELEGATE TO THE CONSTANTINOPLE BOARD OF HEALTH.)

DURING the past few months an epidemic of plague of some severity has been prevailing at Bagdad. The first case of the disease there was seen by the health officer of the town on May 8th last. The patient, a Jew, was said to have been ill during the eight preceding days. Other cases were observed at the same time, but hitherto no light has been thrown on the source from which the infection was introduced into Bagdad. The further course of the outbreak has been as follows:—

	Cases.	Deaths.	Found dead.
Between May 8th and 23rd	20	6	2
In the week ending May 30th	7	7	2
,, ,, ,, June 6th	10	7	2
,, ,, ,, ,, 13th	10	6	3
,, ,, ,, ,, 20th	8	4	3
,, ,, ,, ,, 27th	13	6	2
,, ,, ,, July 4th	15	6	2
,, ,, ,, ,, 11th	8	8	3
,, ,, ,, ,, 18th	4	3	1
,, ,, ,, ,, 25th	6	5	3
,, ,, ,, August 1st	3	2	0
,, ,, ,, ,, 8th	1	2	0
,, ,, ,, ,, 15th	3	2	1
,, ,, ,, ,, 22nd	2	2	2
,, ,, ,, ,, 29th	1	1	1

The totals up to the last-named date were 111 cases with 67 deaths. The high proportion of cases "found dead" cannot escape notice. The written reports from Bagdad tend to show that the measures imposed by the local authorities have not been very adequately carried out. In the early days of the outbreak it was stated that a considerable number of dead rats had been found in the town, and the diagnosis of plague, both in human beings and in rats, was confirmed bacteriologically. Various measures were imposed to prevent the infection spreading outside Bagdad, the most important of which were: a medical inspection of passengers leaving the town by river or road, an additional medical inspection of arrivals in Kerbela (the Shiah Holy City), the prohibition of the transport of corpses from Bagdad to the Shiah Holy Cities of Kerbela and Nedjef, and of the burial of bodies in the interior of the Kiazimieh mosque. Medical visits were also imposed on travellers by the river steamers from Bagdad. The outbreak seems now to be approaching extinction.

The outbreak of plague in Jeddah came to an end in the month of March last. Subsequently to the returns quoted in my letter which appeared in THE LANCET of April 11th (p. 1110) only a single death from the disease was observed there—on March 30th. In Yanbo, on the other hand, the outbreak lasted longer. The following figures are in continuation of those quoted in the letter just referred to:—

	Cases.	Deaths.
From March 12th to March 18th	19	19
,, ,, 19th ,, ,, 21st	6	6
,, ,, 22nd ,, ,, 25th	10	10
,, ,, 26th ,, April 5th	11	11
,, April 6th ,, ,, 14th	2	2
,, ,, 15th ,, ,, 21st	9	9
,, ,, 22nd ,, ,, 28th	25	18
,, ,, 29th ,, May 15th	21	18

Apparently the outbreak in Yanbo died out at the end of May; the total number of cases registered there since the beginning of the epidemic on Feb. 13th was 137 and that of deaths 126.

A few sporadic cases of plague have recently occurred again in Adalia on the south coast of Asia Minor. It will be recalled that in the summer of 1905, and again in August, 1906, a few isolated cases of the disease were observed here. There were none in 1907. In the present instance two cases occurred on July 26th; both the patients were employed in a flour mill and it was stated that an unusual mortality among rats had been observed in the mill and also in other quarters of the town. A third case was seen on August 22nd; the patient was also employed in a mill but in one situated near the port and far removed from the other mill. Finally, a fourth case was reported on Sept. 5th. As in the former outbreaks the exact source of the infection in these cases was unknown.

Plague has recently been prevalent in the Kirghiz Steppes of the Astrakhan government in south-eastern Russia. The returns have been very incomplete, but it is known that early in August nine cases of the disease with four deaths occurred among the Kirghiz in this region. A case of plague also occurred in Odessa early in August but the details have not been published.

Constantinople, Sept. 17th.

MANCHESTER.

(FROM OUR OWN CORRESPONDENT.)

Poor-law Provision and Consumption.

A PAPER was read at the thirty-fourth annual meeting of the North-Western Poor-law Conference held recently at Ulverston by Mr. Macfarlane, chairman of the Chorlton union, on the question of providing, in connexion with the Poor-law, sanatoriums for tuberculous patients. He quoted with approval a statement by Dr. Nathan Raw, that "adequate provision is made by the health authorities for every disease excepting the one that kills most people and which, if taken in time, is more easily cured than most other diseases." An inquiry made the other week at the Chorlton Union Hospital showed the close connexion between pulmonary tuberculosis and poverty, and "proved" also that in the majority of cases poverty, "if not the dominant, was a strong contributory cause of the disease." 30 men out of 100 in the phthisis wards were asked as to their former occupations and the probable cause of their sickness. Eight only had been engaged in the "dusty" or "dangerous" trades regarded as predisposing the workers to pulmonary tuberculosis—viz., one baker, one collier, one iron-grinder, one cabinet-maker, two French polishers, one grey-cloth warehouseman, and one shoe-maker. Of the remaining 22, 18 had been general labourers, who had contracted cold after cold and developed pulmonary tuberculosis. Poverty had compelled them to continue to work in inclement weather, or to forfeit part of the wage which as it was would barely support the wife and children. Mr. Macfarlane thought that there should be combined action between health nocturnal pains, periostitis, and necrosis of the femur, tibia, clavicle, and bones of the forearms; and the joints become distended with fluid and sometimes ankylosed. Gummatous ulceration destroys the eyelids, nose, and ears, producing innumerable varieties of mutilation which may be witnessed every day; and the amount of inherited syphilis is enormous. In every part of the country there are constantly met boys and girls between eight and ten years of age who are thus affected, frequently with osteo-arthritis of both knees. Caries of the bones of the face and of the base of the skull is common, and also blindness due to interstitial keratitis. With regard to the effect on childbirth and infant mortality Colonel LAMBKIN quotes from Dr. C. A. COOK, C.M.S., the calculation that 75 per cent. of the pregnancies of the Uganda women end in abortion or miscarriage, premature labour or stillbirth, or in the death of the infant during the first week after delivery. Parasyphilitic affections are not very common and Colonel LAMBKIN assumes that the disease has not existed in the country for a sufficient length of time to produce any abundance of them. Still, a certain number of tabetic cases have fallen under his observation and "quite a number" of young men with syphilitic histories who were suffering from complete loss of sexual power.

With regard to the causes of the epidemic—for so, indeed, it may be called—Colonel LAMBKIN gives the first place to the supersession by Christianity of the tribal laws and customs which formerly prevailed, under which the liberties of women were greatly restricted and unchastity was severely punished. Christian teachers have brought about the abandonment of polygamy and of a control over female liberty which was formerly exerted, and under which immorality and promiscuous intercourse did not exist. Corresponding with the time of the outbreak of syphilis, the chiefs of the Baganda tribe, the majority of whom had become Christians, decided to remove all such restrictions, as being contrary to Christian teaching, and to set the women free. This was done, and the women were left at liberty to roam about and to do as they liked, with the result of establishing a system of promiscuous sexual intercourse and immorality. The freedom enjoyed by women in civilised countries has gradually been won by them as one of the results of centuries of civilisation, during which they have been educated; and women whose female ancestors had for countless generations been kept under surveillance were not fit to be treated in a similar manner. They were, in effect, merely female animals with strong passions, to whom unrestricted opportunities for gratifying these passions were suddenly afforded. The opinion thus stated is confirmed, it is satisfactory to observe, by competent witnesses who are themselves Christian teachers; and Colonel LAMBKIN cites the testimony of the Rev. J. ROSCOE of the Church Missionary Society, Chief of the Theological College at Kampala, and that of the Very Rev. Père LAANE, Superior of the White Fathers at Entebbe, whose labours for the relief of the sufferers from sleeping sickness have lately called forth a warm eulogium from Mr. HESKETH BELL, the Governor of Uganda. As a second cause the abolition of the punishments formerly inflicted upon offenders against chastity is mentioned and is said to have encouraged the commission of such offences, and thus to have lent itself to the propagation of syphilis amongst the people. Colonel LAMBKIN concludes his paper by a sketch of an organisation which he has established, with the aid of the local chiefs, for the cure of persons suffering from syphilis, and under which treatment rooms will be opened in various localities, while a sufficient regularity of attendance on the part of the patients will be secured through the agency of these chiefs and of the control which they still exert over their people. "Ne quid nimis."

THE NOTIFICATION OF PULMONARY TUBERCULOSIS.

A COMPARATIVELY open secret was disclosed at the International Congress on Tuberculosis at Washington by Dr. A. Newsholme, principal medical officer of the Local Government Board. Dr. Newsholme, speaking on the authority of Mr. Burns, the President of the Local Government Board, made the expected announcement that the Board proposed to put upon Poor-law medical officers the duty of notifying, to all sanitary authorities who requested the information, all cases of pulmonary tuberculosis occurring among patients who are a charge to the parish. Such an order, to be of any use, will also make it compulsory upon the guardians and their staff to notify changes of address of parochial patients suffering from pulmonary tuberculosis, and no doubt the details of such notification will be arranged. It seems to us that a good deal of care will have to be exercised in this latter direction lest anything that looks like the unnecessary segregation of a class should lead to concealment of a certain number of exactly the kind of cases that ought to be under active treatment.

AN EXPERIMENT IN CONTRACT PRACTICE.

THE medical men in the town and suburbs of Bellinzona, who have been making what we should think a somewhat bold experiment in contract practice on extensive lines, have soon discovered to their cost what an inordinate amount of unnecessary trouble thoughtless people manage to give when they only have to pay a fixed sum—usually a very small one—per annum. An arrangement was made whereby the locality was divided into districts, the inhabitants paying a small rate to the local municipal authority, out of which the medical men received from £120 to regards the teaching staff, no further changes are to be found beyond those already recorded in these columns. On the executive side an important change has taken place which will be to the utmost advantage of the College from the public point of view. The treasurership is now held by Mr. Cecil A. Cochrane, M.A. Oxon., a well-known and highly respected business man in the North of England. This is a most important step and one which it is difficult to overestimate. It is to be hoped that this principle of the introduction of public men into the affairs of the College will be more widely applied and that this forward move on the part of the "members" will very soon be followed by other equally necessary and vital changes. Mr. Cochrane will be sincerely thanked by all who have been watching the interests of the College for undertaking to find time to perform this public service. Another very gratifying fact is the addition of the name of Mr. Clement Stephenson, D.Sc., to the council. Mr. Stephenson has been, in the very highest sense, a lifelong friend of the College, and few unfamiliar with the inner workings of the College are aware of the enormous amount of unobtrusive work done in its interests in the past by him. It is only to be regretted that this slight recognition of his efforts to further the interests of the College has been so long delayed.

Assistant School Medical Officer for Newcastle.

A few weeks ago the corporation of Newcastle advertised for an assistant school medical officer at a salary of £200 per annum. A few applications were received and two candidates were selected to appear before a subcommittee of the education committee. One of these wrote regretting his inability to attend; the other was interviewed by the subcommittee but did not obtain the position. The committee has now decided to advertise again, offering a salary of £250 per annum. The original proposal to offer a salary of only £200 per annum was rather sharply criticised at the time when it was made, and it is somewhat surprising that the proposal should have been carried, seeing the demand that there is at the moment for school medical officers and knowing the reputation enjoyed by the corporation for employing highly qualified officers. Considerable satisfaction is felt locally that the committee has reviewed its decision and now offers a resonable remuneration for work that will be in the highest degree important and responsible.

Sept. 29th.

WALES AND WESTERN COUNTIES NOTES.

(From our own Correspondents.)

Cardiff Water-supply.

The water-supply of the city of Cardiff is obtained from the Brecknockshire Beacons, moorland situated some 30 miles distant where there are two impounding reservoirs. The consumption equals about 28 gallons per head of the population daily. Water carriage is universally adopted in the town, though there are still a fair proportion of hand-flushed water-closets. When the Brecknockshire supply was first decided upon it was fully anticipated that in the event of the population increasing in the future as it had in the past a third reservoir would be required, and such was indeed included in the original scheme. During the past few years the necessity for proceeding with the construction of this reservoir has been frequently discussed and the expenditure of large sums of money in other directions has probably been the principal cause of the delay in the realisation of the project. The waterworks engineer of the corporation has recently reported that the proposed works are of such magnitude that six or seven years must elapse before their completion and that by the end of that period the existing supply would be inadequate for the needs of the inhabitants if their numbers increased at the rate anticipated. In order to postpone, if only for a few years, such a serious outlay as that involved in the undertaking, it was suggested by some members of the corporation that some use might be made of the spring water which is constantly being pumped out of the Severn Tunnel by the Great Western Railway Company. This amounts to some 10,000,000 or 12,000,000 gallons daily and occasionally nearly 20,000,000 gallons. A few villages are supplied with about 25,000,000 gallons annually, the railway company use about 160,000,000 gallons for locomotive and other purposes, and the remainder is sent into the river Severn. The water is unfortunately extremely hard, its total hardness being 38 degrees and permanent 14, though by suitable softening processes a considerable reduction is possible. The proposal to use this water, so much of which was running to waste, seemed at one time to contain the solution of a difficult problem, but after investigating the matter very closely and after receiving a report from the medical officer of health (Dr. E. Walford) to the effect that owing to the high degree of permanent hardness the supply would be unsuitable for either domestic or manufacturing purposes, the waterworks committee has unanimously decided that the scheme is wholly impracticable.

County Medical Officer of Health for Devon.

Considerable interest has been taken in the appointment of a county medical officer of health for Devon. Three selected candidates appeared before the Devon county council on Sept. 24th and finally Mr. G. Adkins was elected by a large majority of votes. Mr. Adkins comes of an old Devonshire family, his father being in practice in Yealmpton, near Plymouth, for many years. Mr. Adkins was formerly medical officer of health of Plympton rural district and was deputy medical officer of health of Plymouth.

The Difficulties of Medical Officers of Health.

At the last meeting of the St. Just (Cornwall) urban district council a letter was read from the Local Government Board relating to the report of the medical officer (Mr. R. G. Nesbitt) on the recent outbreak of enteric fever at St. Just and Boscaswell. The Local Government Board stated that it regarded with great dissatisfaction the continued inaction of the council, which by its prolonged delay in providing a wholesome water-supply for the district and neglect in other matters of sanitation, was incurring grave responsibility. The Board urged the council to take into earnest consideration the medical officer of health's recommendations in regard to the water-supply and other sanitary matters. One of the members accused Mr. Nesbitt of "raising a hornets' nest about their ears," and moved a proposition, which was carried, that the Local Government Board should be informed that the council is endeavouring to obtain a supply of water for St. Just and the district.

The Tiverton (Devon) Rural District Council and the Local Government Board.

At a meeting of the Tiverton rural district council, held on Sept. 22nd, a letter was read from the Local Government Board stating that it could not sanction the council's scheme for the sewerage of Bradninch. The Board had previously advised the council that a qualified engineer of practical experience should be called in, but the council had neglected this advice and its sanitary inspector had prepared a scheme.

Insurance against Tuberculosis in Cattle.

The attempt of the National Meat Traders' Association to throw upon the farmers the whole pecuniary responsibility attaching to the inadvertent possession of tuberculous cattle is being viewed with alarm by agriculturists in the West of England. At a meeting recently held at Bristol and presided over by Lord Winterstoke it was unanimously resolved that the proposal of the Meat Traders' Association to throw the whole responsibility upon the farmer was unfair and that farmers, butchers, and auctioneers should combine and make such arrangements by insurance as would protect both the butcher and the grazier. In view, however, of promised legislation it was decided to postpone taking active steps in the matter. For five or six years past the question has been dealt with in a very satisfactory manner by the butchers and farmers in Monmouthshire and to a certain extent by some of those in Glamorganshire. The scheme adopted in these districts is rendered possible owing to the purchases of cattle being made by means of auction sales. The auctioneer deducts from the sums which he hands over to the farmer 1s. for each head of cattle sold and he undertakes to indemnify the butcher to the extent of one half the value of the animal in the event of its being condemned as tuberculous by a sanitary authority within 14 days of the purchase.

Medical Treatment of Cardiff School Children.

In his quarterly report to the Cardiff education authority the medical officer of health (Dr. E. Walford) makes some suggestive remarks in connexion with the amelioration of the

California, while Russia was the only European country affected. In 1905 the mortality from plague in India fell a little below 1,000,000. In Asia its distribution was not materially changed. The disease was brought to Liverpool from Rangoon, to Manchester from Buenos Ayres viâ Hamburg and Middlesbrough, and to Leith. In 1906 a great decrease of plague took place in India, only 332,000 deaths resulting, but the following year was marked by a great increase, 1,200,000 deaths being reported. It invaded new territory in Northern Africa, notably in Tunis and in Algeria. The report includes tables, showing the distribution of the disease year by year in countries and in localities, together with a list of vessels on which cases of plague occurred, with the names of the ports of departure and arrival.

THE USE OF PICRIC ACID IN BURNS.

THE specific action of picric acid in the treatment of burns at first led to the belief that an ideal curative agent had been discovered, but it was soon found that when unwisely used it produced serious toxic symptoms. The treatment of burns is highly important because it is necessary to prevent shock as well as to relieve pain. The value of picric acid in this connexion is described by Dr. C. P. Martin in the *International Journal of Surgery* for August. It has been the custom for many years to relieve the pain resulting from burns by administering morphine, but Dr. Martin finds that the severity of the shock may be diminished and the pain relieved by the use of a picric acid dressing without giving morphine. Sterile gauze, soaked in a solution of picric acid containing 60 grains in 16 fluid ounces of sterile water, should be applied directly to the burned surface, covered with rubber tissue and cotton wool, and finally held in position by a bandage. After 48 hours the dressing is renewed unless any infection has occurred, when the surface should be first washed with a solution containing ten grains of potassium permanganate in 32 fluid ounces of sterile water. Then from day to day the dressing is renewed until the surface looks hard and dry, when the dressings are discontinued and the surface is covered with oxide of zinc, leaving the parts fully exposed to the air. One great advantage in the use of picric acid lies in the fact that the first dressing does not need removing for 48 hours, after which time shock need no longer be feared. The dressing absorbs the discharges from the burn and thereby prevents septic absorption. Any dressing which keeps these discharges in contact with the absorbing surface of a burn invites the onset of severe constitutional symptoms. Picric acid is sterile and antiseptic and stimulates the production of new tissue. The yellow stain produced by picric acid may be removed by first washing the hands in weak ammonia water and then bleaching them with a pure solution of hydrogen peroxide, which may be conveniently applied on cotton wool. The staining of the patient's clothing need not occur if the cotton wool be so arranged that it absorbs the discharges as they escape. As to the fear of poisoning, Dr. Martin believes this to be due to the use of too concentrated solutions of picric acid. In regard to oil dressings he points out that oil is neither sterile nor antiseptic, and it may form a suitable medium for the growth of organisms, even if it be sterilised before use. An oily dressing will not absorb discharges and it requires to be changed after 24 hours as it is then in a septic condition. When the parts have once been bathed in oil it is almost impossible to clean them thoroughly before applying other dressings. Carron oil itself, in Dr. Martin's opinion, has no healing properties and requires to be followed by another dressing if rapid and satisfactory results are to be obtained. In cases of emergency, in fact in all cases of burns, it is necessary that the dressing should be ready to hand. This requirement is well met by picric acid, which may be kept in the form of dry picric gauze, requiring only to be moistened just before it is applied.

MR. CARNEGIE AND MEDICAL HEROES.

THE latest of Mr. Carnegie's apparently inexhaustible benefactions, which is reported to have brought up the sum of his gifts for public purposes to something over £25,000,000, has, he tells us, been prompted by the success of the "Hero Fund" in North America. This has been so great that its founder has decided to extend its benefits to his own land, and it is now common knowledge that this open-handed millionaire has paused for a moment in his endowments of the libraries and other centres of education to hand over one and one-quarter millions of dollars to the Carnegie Dunfermline trustees for the object which he has set forth in a very characteristic letter. He wishes that those many brave men and women who suffer bodily injury during heroic efforts to save human life performed in times of peace "in the British Islands and the waters thereof," shall by means of this fund be put in a financial position a little better, if anything, than was theirs before their act of self-sacrifice until they are able to work again. And if a bread-winner shall have given his life to save some fellow creature his widow and children may claim support from the fund until such time as they can support themselves. The fund may have a higher function than simple compensation, for it may actually rehabilitate some obscure hero who has risen to his opportunity out of a miry past of which he would fain hide the traces. Such a one is to be eligible for his pension so long as he behaves himself without any questions being raised of his antecedents. Mr. Carnegie deprecates strongly any suggestion that his fund shall replace the compensation offered in cases of accident resulting from heroism by private or public agencies already existing. These should bear their burden willingly, he thinks, but he desires to make it absolutely sure that full provision may be made for every case. It is not surprising to anyone who has read the terms of this new trust to learn that it has the support and sympathy of the highest in the land, whose word is to be law in certain questions of its administration. It would, however, hardly concern us to chronicle it, save inasmuch as every premium upon courage and self-sacrifice makes for the well-being of the State, were it not for the fact that Mr. Carnegie in his letter specifies in particular only two classes as being notably productive of heroes, although we are quite sure that he makes no mental distinction between the bravery displayed in time of need by, say, the miner whom he does not mention and the railroad employee whom he does. But his most prominent instance is this: "No action is more heroic than that of doctors and nurses volunteering their services in the case of epidemics." We take it for an especial virtue in Mr. Carnegie that in his benefactions he does not forget the members of a profession the simple exercise of which in the eyes of so large a number of people should bring its own reward, but we must confess to some surprise at his having chosen out an almost routine duty of its practitioners for special illustration of the quality of heroism. It is true that Mr. Carnegie limits his instance to medical ministry during epidemics but we can hardly think that he holds less lightly the action of "doctor and nurse" who attend any patient suffering from a dangerous infectious disorder even though it be not widespread in the community. Indeed, it might be said that their service is less heroic in attending a rich person at a time when they would be liable to the disease, whether they attended him or not, than regards the teaching staff, no further changes are to be found beyond those already recorded in these columns. On the executive side an important change has taken place which will be to the utmost advantage of the College from the public point of view. The treasurership is now held by Mr. Cecil A. Cochrane, M.A. Oxon., a well-known and highly respected business man in the North of England. This is a most important step and one which it is difficult to over-estimate. It is to be hoped that this principle of the introduction of public men into the affairs of the College will be more widely applied and that this forward move on the part of the "members" will very soon be followed by other equally necessary and vital changes. Mr. Cochrane will be sincerely thanked by all who have been watching the interests of the College for undertaking to find time to perform this public service. Another very gratifying fact is the addition of the name of Mr. Clement Stephenson, D.Sc., to the council. Mr. Stephenson has been, in the very highest sense, a lifelong friend of the College, and few unfamiliar with the inner workings of the College are aware of the enormous amount of unobtrusive work done in its interests in the past by him. It is only to be regretted that this slight recognition of his efforts to further the interests of the College has been so long delayed.

Assistant School Medical Officer for Newcastle.

A few weeks ago the corporation of Newcastle advertised for an assistant school medical officer at a salary of £200 per annum. A few applications were received and two candidates were selected to appear before a subcommittee of the education committee. One of these wrote regretting his inability to attend; the other was interviewed by the subcommittee but did not obtain the position. The committee has now decided to advertise again, offering a salary of £250 per annum. The original proposal to offer a salary of only £200 per annum was rather sharply criticised at the time when it was made, and it is somewhat surprising that the proposal should have been carried, seeing the demand that there is at the moment for school medical officers and knowing the reputation enjoyed by the corporation for employing highly qualified officers. Considerable satisfaction is felt locally that the committee has reviewed its decision and now offers a resonable remuneration for work that will be in the highest degree important and responsible.

Sept. 29th.

WALES AND WESTERN COUNTIES NOTES.

(FROM OUR OWN CORRESPONDENTS.)

Cardiff Water-supply.

THE water-supply of the city of Cardiff is obtained from the Brecknockshire Beacons, moorland situated some 30 miles distant where there are two impounding reservoirs. The consumption equals about 28 gallons per head of the population daily. Water carriage is universally adopted in the town, though there are still a fair proportion of hand-flushed water-closets. When the Brecknockshire supply was first decided upon it was fully anticipated that in the event of the population increasing in the future as it had in the past a third reservoir would be required, and such was indeed included in the original scheme. During the past few years the necessity for proceeding with the construction of this reservoir has been frequently discussed and the expenditure of large sums of money in other directions has probably been the principal cause of the delay in the realisation of the project. The waterworks engineer of the corporation has recently reported that the proposed works are of such magnitude that six or seven years must elapse before their completion and that by the end of that period the existing supply would be inadequate for the needs of the inhabitants if their numbers increased at the rate anticipated. In order to postpone, if only for a few years, such a serious outlay as that involved in the undertaking, it was suggested by some members of the corporation that some use might be made of the spring water which is constantly being pumped out of the Severn Tunnel by the Great Western Railway Company. This amounts to some 10,000,000 or 12,000,000 gallons daily and occasionally nearly 20,000,000 gallons. A few villages are supplied with about 25,000,000 gallons annually, the railway company use about 160,000,000 gallons for locomotive and other purposes, and the remainder is sent into the river Severn. The water is unfortunately extremely hard, its total hardness being 38 degrees and permanent 14, though by suitable softening processes a considerable reduction is possible. The proposal to use this water, so much of which was running to waste, seemed at one time to contain the solution of a difficult problem, but after investigating the matter very closely and after receiving a report from the medical officer of health (Dr. E. Walford) to the effect that owing to the high degree of permanent hardness the supply would be unsuitable for either domestic or manufacturing purposes, the waterworks committee has unanimously decided that the scheme is wholly impracticable.

County Medical Officer of Health for Devon.

Considerable interest has been taken in the appointment of a county medical officer of health for Devon. Three selected candidates appeared before the Devon county council on Sept. 24th and finally Mr. G. Adkins was elected by a large majority of votes. Mr. Adkins comes of an old Devonshire family, his father being in practice in Yealmpton, near Plymouth, for many years. Mr. Adkins was formerly medical officer of health of Plympton rural district and was deputy medical officer of health of Plymouth.

The Difficulties of Medical Officers of Health.

At the last meeting of the St. Just (Cornwall) urban district council a letter was read from the Local Government Board relating to the report of the medical officer (Mr. R. G. Nesbitt) on the recent outbreak of enteric fever at St. Just and Boscaswell. The Local Government Board stated that it regarded with great dissatisfaction the continued inaction of the council, which by its prolonged delay in providing a wholesome water-supply for the district and neglect in other matters of sanitation, was incurring grave responsibility. The Board urged the council to take into earnest consideration the medical officer of health's recommendations in regard to the water-supply and other sanitary matters. One of the members accused Mr. Nesbitt of "raising a hornets' nest about their ears," and moved a proposition, which was carried, that the Local Government Board should be informed that the council is endeavouring to obtain a supply of water for St. Just and the district.

The Tiverton (Devon) Rural District Council and the Local Government Board.

At a meeting of the Tiverton rural district council, held on Sept. 22nd, a letter was read from the Local Government Board stating that it could not sanction the council's scheme for the sewerage of Bradninch. The Board had previously advised the council that a qualified engineer of practical experience should be called in, but the council had neglected this advice and its sanitary inspector had prepared a scheme.

Insurance against Tuberculosis in Cattle.

The attempt of the National Meat Traders' Association to throw upon the farmers the whole pecuniary responsibility attaching to the inadvertent possession of tuberculous cattle is being viewed with alarm by agriculturists in the West of England. At a meeting recently held at Bristol and presided over by Lord Winterstoke it was unanimously resolved that the proposal of the Meat Traders' Association to throw the whole responsibility upon the farmer was unfair and that farmers, butchers, and auctioneers should combine and make such arrangements by insurance as would protect both the butcher and the grazier. In view, however, of promised legislation it was decided to postpone taking active steps in the matter. For five or six years past the question has been dealt with in a very satisfactory manner by the butchers and farmers in Monmouthshire and to a certain extent by some of those in Glamorganshire. The scheme adopted in these districts is rendered possible owing to the purchases of cattle being made by means of auction sales. The auctioneer deducts from the sums which he hands over to the farmer 1*s*. for each head of cattle sold and he undertakes to indemnify the butcher to the extent of one half the value of the animal in the event of its being condemned as tuberculous by a sanitary authority within 14 days of the purchase.

Medical Treatment of Cardiff School Children.

In his quarterly report to the Cardiff education authority the medical officer of health (Dr. E. Walford) makes some suggestive remarks in connexion with the amelioration of the form of disease rose from 3·6 per 1000 in 1864 to 3·9 in 1870 and in 1871, since which it has steadily declined to 2·1 per 1000 in 1905 and in 1906; thus the decline in the whole period of 43 years has been equal to 41·7 per cent. in Scotland, against 51·5 per cent. in England and Wales. In Ireland, on the other hand, the tuberculous death-rate, which in 1864 was 27·3 per cent. lower than the rate in England and Wales and 33·3 per cent. below that which prevailed in Scotland, has since increased instead of having declined; the annual rate rose from 2·4 per 1000 in 1864 to 2·9 in 1880, and after varying fluctuations was equally high in 1897, 1898, 1900, and 1904, but fell again to 2·7 in 1905, 1906, and 1907. Thus the recorded death-rate from tuberculous disease in Ireland showed an actual increase of 12·5 per cent. during the 44 years 1864–1907. Calculated in decennial periods it appears that the annual death-rate from all forms of tuberculous disease in Ireland was equal to 2·6 per 1000 in the ten years 1871–80, to 2·7 in 1881–90, and to 2·8 in 1891–1900; during the past seven years of the current decennium the mean annual rate has also been equal to 2·8 per 1000. This increase of fatal tuberculous disease in Ireland, having regard to its marked decline in England and Wales and in Scotland, fully justifies the attention which it is receiving in Ireland, although there are some grounds for doubting whether these statistics afford an entirely trustworthy measure of the true death-rate from tuberculous disease among the Irish population. In the first place the high proportion of emigration from Ireland, mainly of selected young and healthy adults, seriously affects the mortality statistics of that country, and more than probably raises the recorded death-rate from tuberculous disease, in the same manner as it has given rise to alarming reports of the excessive and increasing prevalence of insanity in Ireland. That the long-continued elimination from the Irish population of healthy young adults, even ignoring the return of a certain proportion of such emigrants whose health breaks down abroad, undoubtedly affords some explanation of the absence of decline in the recorded death-rate from tuberculous disease in Ireland, is more or less confirmed by an interesting diagram comparing the rates of mortality from this form of disease in 1905 at different ages in the three divisions of the United Kingdom. This diagram shows that practically the whole of the excess of mortality from tuberculous disease in Ireland during that year occurred at the ages 15 to 35 years, the precise age-period most affected by emigration. The Registrar-General for Ireland, moreover, in his recently issued report calls attention to the important fact that in 1907 no less than 24·9 per cent. of the causes of the registered deaths in Ireland were uncertified, while in England the proportion did not exceed 1·4 per cent., and in Scotland the percentage was not higher than 2·3 in 1905. It is obvious that the value for comparative purposes of the recorded death-rate from tuberculous diseases, and indeed from other forms of disease, must be seriously depreciated by this remarkable and excessive proportion of uncertified causes of death in Ireland."

COMPULSORY INSURANCE OF THE WAGE-EARNING CLASSES IN NORWAY.

THE report of a Government committee appointed in Norway to investigate the proposed workmen's compulsory insurance against ill-health has now been published. The scheme provides for the insurance of all persons whose yearly income does not exceed £66 in the country or £77 in towns, the minimum age for insurance being 15 years and the period of service one week or more. Chronic invalids and sailors in foreign parts are, however, excepted. It is proposed that the payments made to the insurance fund shall be apportioned as follows. The person insured will contribute six-tenths, the employer one-tenth, the commune or county one-tenth, and the Government two-tenths. The Government is also expected to pay £12,500 towards starting the machinery of the scheme. On these terms an insured person may obtain 60 per cent. of his average daily wage for 26 weeks every year, a sum not exceeding £2 16*s.* for funeral expenses, and medical attendance free for himself, wife, and children under 15 years. Gratuitous treatment in hospital is also proposed to be given on a medical practitioner's recommendation. Women who are insured may obtain free medical attendance and pecuniary assistance for four weeks during the lying-in period. It is estimated that the cost will be about 6,500,000 kroner (approximately £330,000), of which over 4,000,000 kroner will be contributed by the workers, while the rest is to be paid by the employers, the commune, and the Government, according to the proportions already mentioned. The scheme will probably be introduced to the Storting as the Government's most important Bill next session. Its various provisions seem to have been carefully considered and it presents the important advantage of encouraging thrift. The population of Norway is only about 2,500,000 and there are no extensive manufacturing industries. The results of the experiment will, no doubt, be observed with much interest by politicians and social reformers in other countries besides Norway.

CARBOLIC ACID IN TETANUS.

Dr. César Allievo of Buenos Ayres reports in *La Semana Médica* of August 13th an interesting case of well-marked tetanus which yielded very promptly to treatment by carbolic acid administered hypodermically. The patient was a middle-aged lady who, ten days after cutting a corn on the great toe of the right foot, was found to be suffering from severe headache with a high temperature and an abscess on the inner aspect of the metatarso-phalangeal joint with great pain and tenderness over the whole of the inner side of the foot. Local anæsthesia was employed and an incision was made with antiseptic precautions, letting out a quantity of thick creamy pus. The wound healed satisfactorily and in a few days the patient was able to leave her bed. About a month after the cutting of the corn she again complained of pain in the whole of the right foot and also in the popliteal and inguinal regions of the same side and two or three days later of headache with difficulty in opening the mouth and stiffness of the neck. On examination the pupils were found to be contracted; there were marked photophobia and general hyperæsthesia, the slightest touch of the right foot or leg, or even arm, producing painful clonic general spasms. There was considerable dyspnœa. The urine contained neither sugar nor albumin. A hot bath and a chloral mixture were prescribed and as it was considered that it was too late to expect much good from antitetanic serum the carbolic acid treatment was decided on and 1·5 cubic centimetres of a 2 per cent. solution of carbolic acid were injected hypodermically on the same evening and repeated early on the next morning. A smaller dose, one cubic centimetre, was administered again at noon and at 4 and at 8 P.M. The symptoms had by that time begun to abate, for although the photophobia and headache were still equally severe, the trismus and contraction of the neck and the reflex spasms were far less marked and there was no dyspnœa. The chloral, which had been given very frequently, seemed to be causing gastric disturbance and so was ordered at longer intervals. On the next day two injections were given of one cubic centimetre and as the chloral continued to produce pain in the stomach it was given by enemata.

the child had died from inanition from insufficient and improper food. At the inquest evidence was given in favour of the authorities of the charitable institution which was responsible for the boarding-out of the child to the effect that "infants are taken from their mothers at the Coombe Hospital and boarded out at about a fortnight old without any medical authority or certificate as to their condition, the mothers being then received into the institution at 8, Lower Leeson-street." The lady inspector added: "My experience is that a large proportion of the infants boarded out in this way die within the first year." And to the foregoing report she subjoined the verdict of the coroner's jury, which contained the following rider: "We do not attach any blame to the nurse. We condemn the practice of the Coombe Hospital in sending out to nurse children at an early stage of life, as we consider they should remain longer in charge of their mothers." Some members having defended and some others having attacked the Coombe Hospital practice in this respect, and contradictory views having been expressed regarding the judgment and the jurisdiction of coroners' juries in general, it was decided to furnish the authorities of the Coombe Hospital with a copy of the verdict of the jury.

Lay Views on Tuberculosis.

A letter recently appeared in a leading newspaper from the pen of a master of a workhouse which is sure to have its full share of attention from the average members of the rural population of our more remote districts at least. It announces "a most remarkable cure of an advanced case of consumption of a lady in Youghal." The patient had (May 13th last) been confined to bed for 11 or 12 weeks; weight had fallen from 8 stones 2 pounds to 6 stones 7 pounds; sputum had been sent to a Dublin bacteriologist for analysis, and consumption bacilli had been found; while the regulation "night-sweats, intermittent high temperature, racking cough, and profuse expectoration all pointed to the dread disease," and were well in evidence. Fortunately, however, the microbes had fallen upon thorny ground, for, as we are informed, "When the patient learned this, being herself a trained nurse and a person of strong mind, she said she would fight the bacilli, and thereupon got out of bed and commenced the Nordrach home treatment of consumption. Her husband procured a plan of the American home sanatorium or 'shack,' and forthwith erected one on the boundary wall of his little garden. ...... Here the patient sleeps with air as pure as if the bed was under the canopy of heaven. ...... Then she took the nourishing food—took it, so to say, artificially, without having any inclination to eat. ...... She now weighs 8 stones 1 pound. ...... Night-sweats and temperature have disappeared, Nature seems to resume her proper functions—all except the appetite for food; but this, according to Nordrach theory, will come in a year or two when the bacilli are completely routed, and not till then will recovery be complete." Wisely has the prophet spoken, as all readers must admit! And the correspondent goes on to say, in concluding: "I am not a doctor, but during my time as master of the Youghal Workhouse I saw a great many cases of consumption, and I have not the slightest doubt in my mind that were it not for commencing the Nordrach treatment the patient referred to would be in her grave to-day." In a country like Ireland this class of document will weigh more with country folk than 50 scientific lectures from anti-tuberculosis crusaders, so that the workhouse master has taken upon himself a heavy responsibility.

Double Tenancies in Belfast.

The Public Health Committee passed the following resolution on Sept. 24th:—

> That where two or more families reside in a house in which sanitary accommodation is only provided for a single family the executive sanitary officer be instructed to prosecute in order to put a stop to what the Revising Barrister described as "disgraceful" and "contrary to morality and decency."

With reference to the evils that arise from double tenancies the Belfast Health Commission reported as follows:—

> On the ground that the upper tenancies have in effect no sanitary accommodation, those double tenancies should be sternly abolished, or the provision of an external stairway from the upper rooms to the yard should be insisted upon. This double tenancy was not alleged to be necessary even on the ground of poverty of the tenants, yet it has been tolerated for years, although the practice is well known both to the Corporation and to the Public Health Department.

Sept. 29th.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

The French Vital Statistics for 1907.

THE vital statistics for 1907 have just been published. The deaths exceeded the births by 19,920, an excess due both to a fresh decline in the number of births, which was 32,878 less than in 1906, and to the increase in the number of deaths, which exceeded those of 1906 by 13,693; these exceeded the deaths of 1905 by 10,025, which in turn were 8968 above those of 1904. In comparison with 1906 the number of live births has diminished in 52 departments and has only increased in five. The departments in which the excess of deaths over births is especially apparent are those which comprise the richest country. The relative increase of the population per 10,000 rose to an average of 18 from 1901 to 1905; it fell to 7 in 1906 and in 1907 was replaced by a decrease of 5 per 10,000. There has been a great increase in the number of departments in which the deaths exceed the births.

The Treatment of Sleeping Sickness.

Professor Laveran of the Pasteur Institute, who has been wholly occupied for several years in investigating sleeping sickness, has communicated recently to the Academy of Sciences in the names of himself and his fellow worker, Dr. Thiroux, a note on the treatment of the disease based on a research upon guinea-pigs that had been injected with trypanosomes. He first used tartar emetic, following Plimmer and Thomson, and found that this drug was rapidly effective in causing the trypanosomes to disappear from the blood-stream. In this manner he was able to cure three out of 13 guinea-pigs which he treated. He then tried giving this drug in combination with atoxyl by hypodermic injection, with even better results, six out of the 13 animals being cured. Professor Laveran and Dr. Thiroux are at present trying the alternate administration of atoxyl and orpiment (sulphide of arsenic) which seems to promise the best results.

Tobacco Poisoning and Pregnancy.

M. Dastre communicated to the Academy of Sciences on Sept. 21st a note by M. Robinson concerning the effect of tobacco poisoning upon pregnancy. It has no effect upon this process in bitches, cats, and mares, but it has an effect upon rabbits and guinea-pigs. It is well known that women employed in tobacco factories run the risk of sustaining certain ill-effects from tobacco poisoning. M. Robinson has instituted an inquiry amongst Eastern women who use tobacco with negative results. Of those who smoke the *narghile* or large quantities of cigarettes—30 or 40 a day—M. Robinson has not found a single case of abortion which could be put down to the tobacco.

The Nursing School of the Assistance Publique.

On Oct. 1st an examination for pupils desirous of entering the nursing school of the Assistance Publique will take place. The candidates will have to undergo a medical examination and will in addition have to pass in dictation, to write a simple essay, and to pass a written examination in simple arithmetic. They will also be examined in sewing. The examination is open to female nurses and to servant girls already in the service of the Assistance, as well as to outside candidates. The school is for resident pupils who are girls of from 18 to 25 years of age and unmarried. Candidates already in the service of the Assistance may be as old as 30 years. Candidates if successful must undertake to serve the Assistance for a term of three years or in default must return the expenses of their keep. During their stay at the school the pupils receive board, lodging, light, firing, and laundry. In the first year they are paid 10 francs per month and in the second year 20. If their conduct in the school is satisfactory they are passed out with a certificate of a nurse of the second class.

Sept. 29th.

ITALY.

(FROM OUR OWN CORRESPONDENT.)

Pestis Bubonica at Trieste.

THE cholera shadows hovering ominously on the horizon are stirring the Board of Hygiene to exceptional vigilance, of cholera if the infection should gain a foothold amongst them. As we wrote last week, there is no ground for alarm lest this should happen in England. The Local Government Board is keeping the port and riparian sanitary authorities fully informed of the extent and topography of the epidemic and has intimated to all such authorities that all necessary steps should be taken under the General Order of Sept. 9th, 1907, relating to cholera, yellow fever, and plague in dealing with vessels arriving from the Baltic and North Sea ports and from Southern Russia.

THE ORIGIN AND PREVALENCE OF ENTERIC FEVER IN THE DISTRICT OF COLUMBIA.

A SECOND report[1] on the origin and prevalence of enteric fever in the District of Columbia embodies the results obtained during 1907, including epidemiological investigations of the disease during the enteric fever season, bacteriological examinations of drinking water, bacteriological and chemical examinations of milk, laboratory tests to assist in the diagnosis of the disease, and examinations of specimens—e.g., ice-cream and shell-fish—in search of bacillus carriers. The results so far indicate that enteric fever will cease to be a problem in any community having clean water and an uninfected milk-supply, if in addition cases of the disease are treated as dangerous to the community. It was found that the drinking water was not responsible for the spread of the infection in the District of Columbia. The disease was largely imported from other States and in many cases it was contracted through contact with persons or with articles handled or soiled by persons in the febrile stage of the disease. Infected milk was found to be one of the important known factors in the spread of the disease. The report concludes with certain recommendations: 1. That all cases and suspected cases of enteric fever should be treated as contagious and dangerous to the community, the treatment including isolation, placarding, and the prompt disinfection of the patient's bedding, discharges, and so on. 2. That laboratory facilities should be provided free of cost to aid physicians in the early diagnosis of the disease and to determine when patients are no longer a menace to the public health. 3. That all milk not "certified" or "inspected" should be pasteurised, under official surveillance, especially during the enteric fever season. 4. That a law should be enacted prohibiting the handling or sale of milk or milk products in any dwelling or in any structure so situated as to render these products especially liable to contamination. 5. That a law should be enacted prohibiting the care of a case of enteric fever in any house where foods or beverages liable to convey the infection are sold or prepared for sale. 6. That in order to furnish a water-supply of a satisfactory grade throughout the year adequate storage reservoirs should be provided, failing which alum should be used as a coagulant during periods of high turbidity.

THE TREATMENT OF LARYNGEAL TUBERCULOSIS.

WE have received a reprint from the *American Journal of the Medical Sciences* (August, 1908) of a paper entitled "Clinical Notes on Laryngeal Tuberculosis," by Dr. Beverley Robinson, clinical professor of medicine in the University and Bellevue Hospital Medical College, New York. Dr. Robinson gives the results of his own experience in the treatment of laryngeal tuberculosis and also gives a short *résumé* of the methods adopted by other physicians. He considers that for the relief of pain caused by abraded surfaces the frequent local use of orthoform is a satisfactory remedy. Fortunately, orthoform is innocuous and so may be freely employed. He also endorses the favourable reports which have been recorded of the good effects of lactic acid when actual ulceration is present. Applied in from 10 to 80 per cent. solution it brings about considerable amelioration if not complete healing of the parts affected. A local anæsthetic is often required before and after its application, and especially is this true whenever curetting has been practised prior to the use of the acid. Dr. Robinson, however, is not an advocate of punching and curetting. In the way of protective and curative treatment he considers two things are essential—namely, rest for the larynx and inhalations. With regard to the former, no doubt exists that this is one of the most important factors in the modern treatment of laryngeal tuberculosis; we consider that it is the most valuable measure that can be employed but it is sometimes difficult to secure the needed rest. As a rule the patient is only too willing to aid the physician by refraining from speech for a considerable period of time, but in some cases a troublesome cough disturbs the rest, and then some additional therapeutical means is necessary. Dr. Robinson writes enthusiastically as to the results of antiseptic inhalations. He advises the long-continued use of the perforated zinc inhaler with inhalations of creasote and alcohol, or, when there is much irritative cough, of beechwood creasote, alcohol, and spirit of chloroform in equal parts. He maintains that he knows of "absolutely no other method, no other local application, no surgical measure, which will afford anything like the same amount of relief to symptoms and hasten and promote cure in suitable cases to the same degree as will the perforated zinc inhaler with the inhaling fluid recommended." Although we do not hold such a strong view on the value of this method as does Dr. Robinson, nevertheless it undoubtedly is often of use as an adjunct to the rest treatment, especially in the relief of cough, which, as we have already said, occasionally retards the good effects brought about by the abstinence from speech.

THE Department of Public Health of Queensland, in a bulletin dated August 22nd, reports that Brisbane was free from plague both in man and in rodents for the week ending August 22nd. The Governor of Mauritius, in a despatch to the Secretary of State for the Colonies, states that three cases of plague were reported during the week ended Sept. 24th. The number of deaths for the week was three.

HASLAR NAVAL HOSPITAL.

DR. T. J. MACNAMARA, Financial Secretary to the Admiralty, visited Haslar Naval Hospital on the afternoon of Sept. 29th at the closing of the last class of naval surgeons, numbering 15, by Inspector-General James Porter, C.B., Director-General of the Royal Navy Medical Service. The class had been instructed by Fleet-Surgeon P. W. Bassett-Smith, assisted by Fleet-Surgeon J. J. Walsh and Staff-Surgeon H. C. Adams. There was a large attendance at the interesting proceedings, including Inspector-General T. D. Gimlette, C.B., Deputy-Inspector-General J. Crowley, Deputy-Inspector-General Craig, Fleet-Surgeon Townsend, Fleet-Surgeon R. Willan, Fleet-Surgeon Bassett-Smith, Rear-Admiral C. G. Robinson, and others.

Inspector-General GIMLETTE said that they had met to be in attendance at the presentation of prizes to the class of surgeons on their entry into the service and Dr. Macnamara had been kind enough to come specially from London to make the presentation. It was his pleasant duty to introduce these young officers and he was very glad to be able to give a good also presented for consideration and the establishment of such institutions is earnestly encouraged. The leaflet is also sent to municipal officers, to proprietors of large works, and to many country physicians. The value of proper clothing, of abstaining from alcohol during lactation and gestation, and the necessity of weighing the baby regularly are also dwelt upon. Every help is promised by the committee to those who wish to establish the above-mentioned institutions. A few figures are appended showing the infant mortality in different districts, according to the method of feeding.

---

[1] Bulletin No. 44, Hygienic Laboratory, Public Health and Marine Hospital Service of the United States, by M. J. Rosenau, L. L. Lumsden, and Joseph H. Kastle. Washington, 1908, pp. 66, with maps and curve charts.

An Important Judgment.

In a suit brought by a medical man against the parents of a patient of full age for recovery of fees for treatment the Court of Justice took a remarkable view and the judgment is important for the profession in Austria. A man, aged 32 years, with a family of two children, fell ill, and during that time his means were so reduced that he could not pay his doctor's bill amounting to some £50. Thereupon the doctor asked payment from the parents, which was refused because the patient had his own home and the parents did not call the doctor to undertake the patient's treatment. The judge, however, decided that parents must not only take care for the children under full age but must also, if the child is of full age and cannot support himself, find the means for his upkeep. The recovery of health is essential for the child to regain his earning capacity, therefore the parents are bound to support him until he is able to earn his living. The age incident must be neglected in such circumstances. Judgment was given in favour of the medical man and the money was paid into the court.

Strike of the Students at the Veterinary College.

The students of the Veterinary College have decided to enter upon a general strike by refusing to attend any lectures and by abstaining from examinations until their grievances are removed. The school is under military supervision, which has no precedent in university administration. The management is therefore military, and as veterinary surgeons are not regarded as the social equals of other officers or of medical men their affairs are treated in a somewhat "off-hand" fashion. The financial aspect of the studies and the expenditure on the teaching staff are very unsatisfactory, the accommodation for dissecting and the clinical treatment of animals are very primitive, and the whole military system is very irksome to the students. Several attempts have been made in vain to bring this university college under the control of the Ministry of Education, when it would take equal rank with the other medical colleges. The conservatism of certain classes affords too powerful an obstacle for rational measures. The students have also tried in vain to obtain the title of "Veterinary Doctor." The military management of the college is said to be responsible for the unsatisfactory progress of scientific life in the veterinary school of Vienna, which 50 years ago was regarded as a model of its kind. Since that time all medical men of any standing have refused to have anything to do with the teaching at the college, and bacteriology as well as parasitology cannot be learned there. The students, in a memorandum presented to the Ministry of War and the Ministry of Education, have explained these facts and desire that the college shall be immediately handed over to the control of the University of Vienna, affording the only hope of a proper revival of veterinary study. Should their wishes be not complied with within a certain time they threaten to cease their studies altogether. This would be a very serious matter for the army, where the veterinary service is a branch of ever-growing importance.

Sept. 27th.

AUSTRALIA.

(FROM OUR OWN CORRESPONDENT.)

The Proportion of Fat in the Milk-Supply.

THE Food Standards Committee under the Pure Foods Act in Victoria fixed the requisite fatty solids for milk at 3·5 per cent. The Master Dairyman's Association has protested that this is excessive and has asked that it should be reduced to 3·3 from August 15th to April 15th in each year. It submits that during this period the amount of fat solids is much less than during the remainder of the year. The standard was fixed originally on the result of an average of 3·9 from 2000 samples taken throughout the State. The association contends that this is not a true foundation. It points out that in England the standard is 3 per cent. and the New Zealand producers are protesting that 3·25 is too high and suggest that 3 per cent. is a fair figure. Last year a deputation from the same body asked for a 3·3 standard all the year round. The Food Standards Committee has declined to lower the standard. The chairman, Dr. Norris, said: "Concerning the standard in England and most European countries whatever may be the pressure of circumstances which fixes it at its present ridiculously low rate the analyses of a leading dairy company in London show the following average composition for 200,000 samples: total solids, 12·9; fats, 3·9."

Private Hospitals.

In introducing a Bill to regulate private hospitals in New South Wales Dr. Mackellar said that there were 107 lying-in homes in Sydney and 334 in the whole State. Perhaps 10 per cent. of these were efficient. His Bill aimed at insuring absolute and not relative cleanliness in these institutions. Quite a number of these "homes" were under suspicion. A detective with 15 years' experience had sworn that he knew six men and 30 women in Sydney and the suburbs who were abortionists and the majority were connected with "lying-in homes." That, he thought, was a strong argument for State supervision.

The Victorian Sanatorium for Consumptives.

At the annual meeting of the friends and supporters of the Victorian Sanatorium for Consumptives the committee regretted that the public support which was required had not been forthcoming. The number of patients treated between July, 1905, and the present date was 544. The committee complained that during this period the institution had been subjected to persistent attacks by one section of the press which, though fully and convincingly disproved, had had a prejudicial effect on the public. The committee stated that the Premier had intimated that unless the recommendations of the inspector of charities, the main feature of which was the abolition of paying patients, were adopted the Government grant would be withheld. It had informed the Premier that it could not see its way to undertake such a responsibility unless under complete guarantee. It reluctantly advised that the institution should be closed. The institution, which comprised a winter home at Echuca and a summer residence at Mount Macedon, was formerly largely under the direction of one medical man. This gentleman subsequently severed his connexion with it and remained hostile to the new management. The main objections urged against the institution were that patients were subjected to varying conditions according as they were or were not able to pay for maintenance and that the practice of moving the establishment from one place to another was needlessly expensive. The Echuca quarters were unfavourably regarded by experts. The motion to close the establishment was carried but the Premier has since conferred with the late chairman of the sanatorium committee and it is probable that the Mount Macedon establishment will be reorganised and carried on with Government aid as a purely charitable institution.

A Dying Race.

According to the report of the Aborigines Protection Board for the year ending Oct. 31st, 1907, there were in New South Wales 2347 full-blood aboriginals. Of these 939 were males, 669 females, and 739 children. These with 4613 half-castes make up a total of 6960, as against 7072 the previous year, a decrease of 112. Among full-blood aboriginals the deaths exceeded the births by 60. One of the most important questions which the Board has to face is that of the large number of half-caste and other children (some almost white) at the various stations. Under present conditions, though much has been done for some of them as regards primary education, they are to a large extent growing up in idleness and under the influence of ill-regulated parents. The report says that, "an attempt will be made to solve what is undoubtedly a difficult problem."

Generous Victors in a Libel Action.

A somewhat unusual action for libel was heard recently at Daylesford (Victoria) before Judge Eagleson. Mrs. Mary Roberts had published a letter in a local paper making serious statements reflecting on the management of the Daylesford Hospital in matters of the food and accommodation supplied fever, but not one from small-pox. The deaths referred to these epidemic diseases during the week were equal to an annual rate of 1·7 per 1000, against rates declining from 4·3 to 2·2 in the four preceding weeks; in London the death-rate from these diseases last week did not exceed 1·6. No death from any of these epidemic diseases was registered last week in Derby, Hornsey, Reading, Bournemouth, Hastings, Burton-on-Trent, or in Stockton-on-Tees, whereas the annual death-rates therefrom ranged upwards in the other large towns to 3·8 in Blackburn and in Tynemouth, 3·9 in Great Yarmouth, and 4·0 in Hull. The deaths attributed to diarrhœa in the 76 towns, which had steadily declined in the five preceding weeks from 1134 to 507, further fell to 353 in the week under notice; the highest death-rates last week from this cause were 2·9 in Wigan, 3·0 in Burnley, 3·5 in Hull, and 3·8 in Tynemouth. The 42 fatal cases of whooping-cough showed an increase of four upon the low number in the previous week, and were equal to an annual rate of 1·1 in Walsall. The 39 deaths referred to diphtheria showed, on the other hand, a decline of four, including 15 in London and its suburban districts, four in Manchester and Salford, and two each in Portsmouth, Southampton, and King's Norton. The 35 fatal cases of "fever" exceeded the number in any previous week of this year; 11 were returned in London and its suburban districts, four in Bolton (equal to an annual rate of 1·1). and two each in Liverpool, Birmingham, and Bradford. The fatal cases both of measles and of scarlet fever showed a slight decline from the numbers in the previous week; those of measles in Warrington were, however, equal to a rate of 1·5, and scarlet fever caused three of the deaths in Merthyr Tydfil, equal to a rate of 2·0 per 1000. The number of scarlet fever patients under treatment in the Metropolitan Asylums and the London Fever Hospitals, which had been 2855, 3005, and 3285 in the three preceding weeks, had further increased to 3467 on Sept. 26th; the number of new cases of this disease admitted to these hospitals during the week under notice were 565, against 395, 472, and 625 in the three previous weeks. The deaths in London referred to pneumonia and other diseases of the respiratory organs, which had been 102, 124, and 137 in the three preceding weeks, further rose to 138 last week, but were 19 below the corrected average number in the corresponding week of the five years 1903–07. The causes of 42, or 1·0 per cent., of the deaths registered in the 76 towns last week were not certified either by a registered medical practitioner or by a coroner. All the causes of death were again duly certified in London, Leeds, Bristol, West Ham, Bradford, Newcastle-on-Tyne, Nottingham, Leicester, and in 50 other smaller towns during the week under notice; 11 uncertified causes of death were, however, registered during the week in Birmingham, five each in Liverpool and Blackburn, and three in Manchester.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in eight of the principal Scotch towns, which had been equal to 13·7 and 14·4 per 1000 in the two preceding weeks, declined again to 13·5 in the week ending Sept. 26th. During the 13 weeks of the past quarter the annual death-rate in these eight towns averaged 13·8 per 1000 and exceeded by 0·4 the mean rate during the same period in the 76 English towns. Among the eight Scotch towns the death-rate during the week under notice ranged from 9·9 and 11·9 in Leith and Perth to 14·1 in Glasgow and 16·4 in Dundee. The 475 deaths in the eight towns showed a decline of 33 from the number in the previous week, and included 59 which were referred to the principal epidemic diseases, against numbers declining from 107 to 65 in the five preceding weeks; of these 59 deaths, 35 resulted from diarrhœa, nine from whooping-cough, eight from diphtheria, four from "fever," two from scarlet fever, and one from measles, but not one from small-pox. These 59 deaths were equal to an annual rate of 1·7 per 1000, corresponding with the mean rate from the same diseases in the 76 large English towns. The deaths attributed to diarrhœa in the eight Scotch towns, which had been 64, 52, and 35 in the three preceding weeks, were again 35 last week; of these, 14 occurred in Glasgow, six in Aberdeen, five in Edinburgh, and three both in Dundee and in Paisley. The nine fatal cases of whooping-cough showed a further decline from recent weekly numbers; eight were returned in Glasgow. The eight deaths from diphtheria, on the other hand, showed a further slight increase upon recent weekly numbers, and included five in Glasgow, two in Edinburgh, and one in Paisley. The four deaths referred to "fever" were fewer by five than those returned in the previous week, two being certified as enteric and two as cerebro-spinal meningitis; all these four deaths from "fever" occurred in Glasgow. The fatal cases both of measles and of scarlet fever were again below the average. The deaths referred to diseases of the respiratory organs in the eight towns, which had been 44 and 73 in the two previous weeks, declined again to 59 in the week under notice, and were within one of the number returned in these towns in the corresponding week of last year. The causes of 15, or 3·2 per cent., of the deaths registered in the eight towns during the week were not certified; in the 76 English towns during the same week the proportion of uncertified causes of death did not exceed 1·0 per cent.

HEALTH OF DUBLIN.

The annual rate of mortality in Dublin, which had declined in the five preceding weeks from 24·1 to 19·3 per 1000, rose again to 20·8 in the week ending Sept. 26th. During the 13 weeks of the past quarter the death-rate in Dublin averaged 19·9 per 1000; the mean rate during the same period did not exceed 12·5 in London and 12·9 in Edinburgh. The 157 deaths of Dublin residents during the week under notice showed an increase of 11 upon the number returned in the previous week, and included 18 which were referred to the principal epidemic diseases, against numbers declining from 44 to 21 in the five preceding weeks. These 18 deaths were equal to an annual rate of 2·4 per 1000; the rate during the week from the same diseases did not exceed 1·6 in London and 1·3 in Edinburgh. Of the deaths from these epidemic diseases in Dublin during the week under notice, 12 resulted from diarrhœa, four from measles, and one each from whooping-cough and "fever," but not one from scarlet fever, diphtheria, or small-pox. The deaths attributed to diarrhœa, which had declined in the five preceding weeks from 39 to 16, further fell last week to 12. The fatal cases of measles rose again to four last week, against numbers declining from eight to three in the four previous weeks. The 157 deaths from all causes during the week included 45 of infants under one year of age and 32 of persons aged upwards of 60 years; the deaths of infants exceeded the number in the previous week by 14. Five inquest cases and three deaths from violence were registered; and 61, or 32·5 per cent., of the deaths occurred in public institutions. The causes of six, or 3·2 per cent., of the deaths registered during the week were not certified; in London the causes of all the 1225 deaths were duly certified, while in Edinburgh the proportion of uncertified causes of death was 3·7 per cent.

THE SERVICES.

Royal Navy Medical Service.

THE following appointments are notified:—Fleet-Surgeon: A. H. L. Cox to the *President*, additional, for three months' course of study at the West London and King's College Hospitals.

Special Reserve of Officers.

The undermentioned officer, having assented to be transferred, is appointed to the Special Reserve of Officers from the date stated, retaining the rank and seniority which he held while in the Militia:—The Durham Royal Field Artillery, from The Durham Royal Garrison Artillery (Militia) (dated July 5th, 1908): Surgeon-Lieutenant-Colonel James Rawlings.

Territorial Force.

Royal Army Medical Corps.

Lieutenant-Colonel and Honorary Colonel Francis Lawrance Stephenson, C.B., from the Honorary Colonelcy of the Eastern Command, Woolwich Companies, Royal Army Medical Corps (Volunteers), is appointed to the Honorary Colonelcy of the Royal Army Medical Corps of the 2nd London Territorial Division, with precedence as in the Volunteer Force (dated April 1st, 1908).

and more recently as a magistrate for the borough of Poole Dr. Alderson leaves a widow, two daughters, and three sons. Two of his sons are members of the medical profession.

The funeral took place on Sept. 8th at All Saints' Church, Branksome Park, Bournemouth. Many friends and representatives from the public bodies in Poole to which Dr. Alderson belonged were present, Dr. Alderson's youngest son taking a part in the service.

Deaths of Eminent Foreign Medical Men.—The deaths of the following eminent foreign medical men are announced: Dr. Alexander von Poehl, professor of pharmacology in the St. Petersburg Military Medical Academy, whose name is well known in connexion with the introduction of spermin and many other remedies prepared from various organs of animals.—Dr. Joseph Eichberg, professor of medicine in the Miami Medical College, Cincinnati.—Dr. Dubisson, physician to the St. Anne's Asylum, Paris.—Dr. J. Reboul, surgeon to the Nimes Hospitals.

Medical News.

Foreign University Intelligence.—*Berlin:* The title of Professor has been conferred on Staff-Surgeon Dr. Kimmle, the general secretary of the German Red Cross Societies; Senior Staff-Surgeon Dr. Steudel who has made important researches in the department of tropical medicine; Dr. Johannes Ruge who was for many years assistant to the late Professor Gerhardt and who since then has been bath physician at Kudowa; and on Dr. Carl Oppenheimer, assistant in the Physiological Institute of the Agricultural Department. Dr. Englemann, Director of the University Physiological Institute, proposes to retire at the conclusion of the current winter session.—*Bologna:* Dr. Filippo Lussana has been recognised as *privat-docent* of Experimental Physiology.—*Bordeaux:* Dr. Gentes, *agrégé*, has been appointed Professor of Anatomy.—*Chicago (College of Physicians and Surgeons):* Dr. Daniel N. Eisendrath, Assistant Professor, has been appointed to the chair of Surgery.—*Cracow:* Dr. Julien Talko Hryncewicz, has been appointed Extraordinary Professor of Anthropology.—*Kiel:* Dr. K. von Korff, *privat-docent* of Anatomy, has been granted the title of Professor.—*Naples:* Dr. Sergio Pansini, Extraordinary Professor of Medical Diagnostics, has been promoted to an Ordinary Professorship.—*Parma:* Dr. Emilio Santi of the Florence Medical School has been recognised as *privat-docent* of Midwifery and Gynæcology.—*Pavia:* Dr. Giulio Ascoli of the Genoa Medical School has been recognised as *privat-docent* of Internal Pathology.—*Prague (German University):* Dr. Kleinhans has been appointed Ordinary Professor of Midwifery and Gynæcology in succession to Professor von Franqué who is going to Giessen.—*Rome:* Dr. Giuseppe Cirincione, Professor in the Palermo Medical School, has been appointed Professor of Ophthalmology.—*Sienna:* Dr. Eugenio Centanni, Extraordinary Professor of General Pathology, has been promoted to an Ordinary Professorship.—*Tomsk:* Dr. Alexandrovich Dochevski, *privat-docent*, has been promoted to be Extraordinary Professor of Special Pathology and Therapeutics.—*Toronto:* Dr. Robert D. Rudolf, Assistant Professor of Medicine, has been appointed to the Chair of Therapeutics.—*Turin:* Dr. Giuseppe Satta has been recognised as *privat-docent* of Pathological Chemistry.—*Utrecht:* Dr. J. E. Grevers of Amsterdam has been appointed Lecturer on Odontology.—*Vienna:* Dr. Rudolf Kraus, *privat-docent* of General and Experimental Pathology, has been promoted to an Extraordinary Professorship.

Literary Intelligence.—Messrs. P. S. King and Son have in the press, to be published early in October, a brochure on the Sweating of Women Workers. Besides general information on the subject it will contain a popular digest of the report of the Select Committee of the House of Commons, just published, and Mr. Henderson's Bill on Sweated Industries. The author of the treatise is Mr. James Samuelson of the Middle Temple.—Messrs. Baillière, Tindall, and Cox will have ready for publication next week a volume comprising a series of articles by British, American, and European experts treating on "Tuberculosis in Infancy and Childhood." The volume is edited by Dr. T. N. Kelynack. The same publishers will also issue the seventh edition of Rose and Carless's 'Manual of Surgery." This has been thoroughly revised, with the inclusion of many new and original illustrations.

The Royal Waterloo Hospital.—H.S.H. Prince Alexander of Teck will occupy the chair at the next meeting of the special appeal committee of the Royal Waterloo Hospital on Thursday, Oct. 8th, at 11.30 A.M., at Belfast Chambers, Regent-street, W.

Charing Cross Hospital Medical School.—The following entrance scholarships have been awarded: Epsom scholarship (60 guineas), Arthur M. Jones; Huxley scholarship (50 guineas), Evelyn A. Sutton. Entrance scholarships: Edward H. Morris (30 guineas), Charles E Williams (dental) (30 guineas), Kenneth V. Smith (20 guineas), and a Universities scholarship of 50 guineas, Thomas Beaton.

The late Dr. H. Montague Murray.—On Sunday next, Oct. 4th, after the close of the morning service (about 12.20 P.M.) at the King's Weigh House Church, Duke-street, Grosvenor-square, W., there will be unveiled a mural brass to the memory of the late Dr. Montague Murray, senior physician to Charing Cross Hospital. The brass bears the following inscription:—

To the Memory of HUBERT MONTAGUE MURRAY, M.D., F.R.C.P., Physician to Charing Cross Hospital, Treasurer of this Church,
Who died November 25, 1907, aged 52 years.

"How happy is he born or taught
Who serveth not another's will;
Whose armour is his honest thought
And simple truth his highest skill"
—*Wotton.*

Medical Sickness and Accident Society.—The usual monthly meeting of the executive committee of the Medical Sickness, Annuity, and Life Assurance Society was held at 6, Catherine-street, Strand, London, W.C., on Sept. 18th. There were present: Dr. F. de Havilland Hall, in the chair; Dr. M. G. Biggs, Dr. M. Greenwood, Mr. J. Brindley James, Dr. W. A. Dingle, Mr. F. S. Edwards, Dr. W. G. Dickinson, Dr. F. C. Martley (Dublin), Dr. W. Knowsley Sibley, Dr. H. A. Sansom, Dr. J. W. Hunt, Dr. St. Clair B. Shadwell, Dr. F. J. Allan, Dr. F. S. Palmer, Mr. Edward Bartlett, and Dr. J. B. Ball. The accounts produced show, as usual, a marked diminution in the amount of sickness compared with the experience of the spring of the year. The difference this year is greater than usual as the influenza epidemic added largely to the sickness disbursements in the first three months of the year. The number of new members is exceptionally large. Last year made a record in this respect, but there is every reason to hope that the new proposal list for 1908 will show a still larger total. Prospectuses and all other particulars may be obtained on application to Mr. F. Addiscott, Medical Sickness and Accident Society, 33, Chancery-lane, London, W.C.

London County Council Scholarships for Students of Midwifery.—In January, 1909, the London County Council will proceed to award not more than six scholarships to students in midwifery. Candidates must furnish satisfactory evidence as to character, must be not less than 24 and less than 40 years of age on July 31st, 1909, and must be certified by the Council's medical officer as being in good health. They must be resident at the time of application and award within the area of the administrative County of London. They must also be prepared to satisfy the Council as to their need for pecuniary assistance for the purpose of training as midwives. They will be required to pass a qualifying examination in writing from dictation and elementary arithmetic. This will be held on Friday, Nov. 13th. The value of the scholarships will be £25, this sum being payable to the institution selected by the applicant in part discharge of the fee for board, lodging, and tuition. The course of training, including practical work at the institution, will extend over a period of six months. The scholarships must be held at the institutions recognised by the Central Midwives Board and approved by the Council. Forms of application and further information may be obtained on application from the

March 31st, 1908). The Highland: Surgeon-Lieutenant Edward E. Brown resigns his commission (dated March 31st, 1908). 3rd Lancashire: The undermentioned officer resigns his commission (dated March 31st, 1908): Surgeon-Lieutenant Thomas M. Scott. 1st Orkney: Surgeon-Lieutenant George R. C. Russell resigns his commission (dated March 31st, 1908).

Royal Engineers (*Volunteers*).—1st Aberdeenshire: Surgeon-Captain Albert Henderson resigns his commission (dated March 31st, 1908). 2nd (Earl of Chester's) Volunteer Battalion, The Cheshire Regiment: Surgeon-Captain Andrew MacLennan resigns his commission (dated March 31st, 1908): 3rd Volunteer Battalion, The Cheshire Regiment: The undermentioned officer resigns his commission (dated March 31st, 1908): Surgeon-Captain Thomas A. Rothwell. 1st Volunteer Battalion, The Essex Regiment: Surgeon-Major St. Clair B. Shadwell is granted the honorary rank of Surgeon-Lieutenant-Colonel (dated March 30th, 1908): Surgeon-Major and Honorary Surgeon-Lieutenant-Colonel St. Clair B. Shadwell resigns his commission, with permission to retain his rank and to wear the prescribed uniform (dated March 31st, 1908). 5th Volunteer Battalion, The Durham Light Infantry: Surgeon-Major Andrew A. Abraham is granted the honorary rank of Surgeon-Lieutenant-Colonel (dated March 30th, 1908). Surgeon-Major and Honorary Surgeon-Lieutenant-Colonel Andrew A. Abraham resigns his commission, with permission to retain his rank and to wear the prescribed uniform (dated March 31st, 1908). 3rd (Morayshire) Volunteer Battalion, Seaforth Highlanders (Ross-shire Buffs, The Duke of Albany's): Surgeon-Lieutenant John Bruce resigns his commission (dated March 31st, 1908). 4th (Donside Highland) Volunteer Battalion, The Gordon Highlanders: The undermentioned officers resign their commissions (dated March 31st, 1908): Surgeon-Lieutenant William Henry, Surgeon-Lieutenant Phad E. Howie, and Surgeon-Lieutenant Samuel G. Davidson. 3rd (Renfrewshire) Volunteer Battalion, Princess Louise's (Argyll and Sutherland Highlanders): Surgeon-Captain Charles Whish resigns his commission (dated March 31st, 1908). 2nd Tower Hamlets Volunteer Rifle Corps: Surgeon-Lieutenant Hubert S. Stockton resigns his commission (dated March 31st, 1908).

TERRITORIAL OFFICERS' DECORATION.

The *London Gazette* of Sept. 29th contains an announcement of the institution of a new decoration for officers of the Territorial Force to be entitled the Territorial Decoration and to consist of an oak wreath in silver, tied with gold and having in the centre the Royal Cipher and Crown in gold. The Decoration is to be suspended on the left breast from a silver oak bar-brooch by a green riband of one and a half inches in width with a yellow stripe down the centre.

Correspondence.

"Audi alteram partem."

THE MEASUREMENT OF "T.R."

To the Editor of THE LANCET.

SIR,—At the risk of being likened to the member of a jury who declared that he had never met 11 more obstinate men than his fellow jurors, may I be permitted to protest against formulating the doses of T.R. in terms of its solid constituents—that is, in fractions of a milligramme of the bacterial matter? Is not "T.R." the designation of a fluid prepared from tubercle bacilli that have already undergone a certain extractive process, and as a fluid is not the dose most conveniently described in terms of its volume? The effect of administering a certain volume of T.R. under given conditions has been definitely ascertained and the percentage composition of its residue on evaporation is not clinically a matter of much importance.

T.R. *was* supposed to contain 1 per cent. of dried bacterial matter, but about a year ago Sir A. E. Wright discerned a handwriting on the wall "*Tekel*—the residue is weighed in the balance and found wanting," the exact deficit being four-fifths of its supposed weight. The solid content only amounted to 0·2 per cent. Some dealers still recognise and use the old imaginary estimate under the designation, "the old nomenclature." If I am right in assuming that "T.R." describes the whole preparation, strictly speaking 1-1000th *milligramme* means the amount of the fluid that scales that weight, but under "the old nomenclature" it means 100 times that amount, and according to the usage now prevalent, 500 times. (Could there be worse confusion?) 1-1000th *cubic centimetre* T.R. has, and only can have, everywhere and for all, but one meaning.

I am, Sir, yours faithfully,
W. D. ANDERSON.

Oban, Sept. 28th, 1908.

THE RELATIONSHIP OF BERI-BERI TO SCURVY.

To the Editor of THE LANCET.

SIR,—Some interesting notes in THE LANCET of June 27th last, p. 1838, by Dr. D. M. Macrae upon scurvy in South Africa make mention of the fact that some observers have spoken of scurvy as associated with a form of beri-beri. I was in North-West Australia during 1890, 1891, and 1892 as medical officer to Messrs. Streeter's Pearling Fleet, Broome being the centre of operations, and an epidemic of beri-beri occurred with symptoms which pointed very strongly to a scorbutic origin. The disease affected chiefly the lugger boys who were shipped from Koepang in the Malay Archipelago, although cases appeared amongst the Japanese pearl-divers. The cooks, Chinamen generally, the West Australian aboriginals, and the "white" men who lived aft in the schooners seemed to be exempt from the disease. The disease manifested itself only when the men had been many months at sea. The vessels were kept clean apparently and well ventilated though they were infested with cockroaches. The opportunity for the patients to be shipped ashore came only when the schooner was loaded up with pearl and had to put into port for transhipment of shell as well as for provisions, which consisted chiefly of rice and tinned meats. The sick formed up in *queue* and shambled into large tents provided for them, where their dietary was altered and included fresh meat, bullock's or kangaroo's flesh and fresh raw lime juice. The majority soon showed signs of improvement and in time were able to return to sea again. Those whose symptoms remained unrelieved always complained of "sakkeet dadda" or "seki dadda." The English translation of this Malayan phrase I am unable to give, but it implied a deep-seated pain or subjective suffocative sensation referable to the epigastric or midsternal regions. I came to regard the finger pointing to this region as the finger of death, for it foreboded with absolute certainty death in a very short time. The signs and symptoms that were obvious enough to the naked eye were the wan and languid appearance of the patients, whose movements were slow and intellects dull, facial expression lost, the swelling of the face and bronzing of the cheeks, while the conjunctivæ took a chocolate hue, with a marked streak of this colour transversely across the sclerotics. The body was apparently well nourished, although the ankles and legs were greatly swollen and œdematous and pitted on pressure, especially over the tibiæ, and were painful, especially at night, over the internal malleoli and inner condyles. A bronzing or pigmentation was visible in the buccal mucous membrane and the gums were reddish and spongy and in some cases overgrown. The tongue was foul, furred, flabby, and indented by the teeth, and the breath had the odour of skimmed milk. In a case of fatal termination the symptoms would be obstinate constipation and vomiting and dyspnœa. Then anasarca developed and the abdomen became prominent. The face and eyes were puffy and in this stage the pupils were contracted. Later, when the patient could scarcely stand, the dyspnœa increased to such an extent as to cause almost continuous moaning and groaning. This hard fight against death ended by a long-drawn sharp groan. Although consciousness was retained up to the last few minutes there were a sluggish mentality and difficulty in answering questions. The eyelids previously to death were ptosic. The ultimate signs of dissolution were tetanic movements all over the body and opisthotony, clonic jerks of the tongue, œsophageal spasm, and last of all a tremor of the muscles of the extremities which seemed to indicate a poisoning of the nerve centres. As to the nature of the poison, well, I will leave that out, although I am inclined to think of it as a metabolic carbonaceous product. No albumin was found in the

GLENNY, ELLIOTT THORNTON, M.B., B.S. Lond., L.R.C.P., M.R.C.S., has been appointed Medical Officer to the Ashley Down (Muller's) Orphanage Home, Bristol.

HANSON, ALFRED, M.R.C.S., L.R.C.P. Edin., has been appointed a Medical Inspector of Schools for Swansea.

N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

same principle and for the very same reasons of moving gently, with the result that we are as we are. In Ireland we have tremendous leeway to make up in matters pertaining to sanitation, and the progress of tuberculosis in the three countries shows this more than anything else. It might have been different had even a minority of the sanitary authorities had the advantage of the presence and assistance and encouragement of such men as representatives of the ratepayers as Dr. McWalter, but unfortunately they had not, nor are they likely to have, so that it is absolutely hopeless to expect many boards to follow in the wake of the South Dublin board of guardians, and if we are content to adopt this method I would just like to ask the learned doctor how long does he expect it would take to reduce the mortality from tuberculosis from 2·7 to 1·35 and how many people would succumb to it in the meantime!

I am, Sir, yours faithfully,
SAMUEL AGNEW, M.A., M.D. R.U.I.,
Medical Superintendent Officer of Health, Lurgan.
Lurgan, Sept. 21st, 1908.

To the Editor of THE LANCET.

SIR,—"For the love of heaven, gentlemen," said Jowett to some cocksure junior Fellows one day, "conceive it possible that you may be mistaken." With profound humility I submit the advice to Sir John Byers and to the other distinguished men who laud compulsory notification of tuberculosis as the most important step towards ridding Ireland of that plague.

But let me reply to Sir John's points. He inquires, are not the many meetings which have been held under Lady Aberdeen's campaign—in which compulsory notification was commended—a proof of the desire of the country for that step! I deny the conclusion; al the meetings were composed of three classes—those attached in one way or other to the Viceregal Court, some extremists on the medical side who had never studied the economic problem of providing for the phthisical, and a residue of well-meaning people who had never considered what compulsory notification really means. The whole business had such a philanthropic aim, and was indeed so well intended, that nobody cared to raise objections, but when as a result of these mutual admiration meetings an effort is made to pass penal legislation for a whole country it is time to protest.

Sir John Byers refers me to the experience of compulsory notification at Sheffield, New York, and elsewhere. I am not sure if Sir John was at the Sheffield meeting of the British Medical Association, but everyone could see that compulsory notification may be an excellent thing in a city where a whole population works together in crowded factories, and a doubtful experiment for a whole country where the conditions are absolutely different. If Sir John can point out any entire country where compulsory notification of phthisis prevails and causes no hardship we must be impressed by it, but the example of an odd city goes for nothing. The fact that in 1864 the Irish death-rate from tuberculosis was the lowest in the three kingdoms, although no sanitary precautions were heard of, whereas now, after a quarter of a century's sanitary legislation, it is the highest, gives one to think furiously about the net result of these measures in actual practice.

I am, Sir, yours faithfully,
Dublin, Sept. 27th, 1908. J. C. MCWALTER.

"SENSATIONAL JOURNALISM."

To the Editor of THE LANCET.

SIR,—The prominence of "tragic deaths," "murders," and "suicides" in our daily papers is appalling. Every day when one picks up the morning newspaper and opens it at the summary and leading articles one's eye cannot fail to be attracted by the large letters on the same page stating reports as above. Such reading, to those of nervous temperament, weak-minded, and neurasthenic, is more than harmful, as it dictates to them the ways and means of acting likewise, and many, I think, have knowledge put into their minds upon which they act sooner or later.

When I was a lad in 1870–1880, or a quarter of a century ago, such reports were seldom seen or heard of. Now such statements are passed from mouth to mouth, in the motor, train, or tramcar, and appear to be the topic of the day and hour. Could not these horrors be hidden away discreetly on another page and many details omitted altogether? Surely the medical profession ought to try to see what can be done to rectify matters, thereby helping the weak-minded and preventing atrocities being committed. It is as much the doctor's duty to prevent, when possible, sickness as it is to relieve and cure it. I write from experience, as lately patients of mine on reading the papers, and it is difficult not to let them get them, have been advanced from the subacute to acute stage of suicidal mania.

I am, Sir, yours faithfully,
Buxton, Sept. 25th, 1908. JOHN MCOSCAR, L.R.C.P. Lond.

RUPTURE OF THE LIGAMENTUM PATELLÆ.

To the Editor of THE LANCET.

SIR,—On looking over the last few numbers of THE LANCET I see that in the issue dated Sept. 12th you have an annotation on two cases of rupture of the ligamentum patellæ, which is followed, in the issue of Sept. 19th, by a letter from a Leicester correspondent reporting another case. These have prompted me to send you notes of the following case which occurred on board of a mail steamer of which I was surgeon at the time.

The patient was a man aged 23 years. On June 19th, 1908, one day out from Punta Arenas, he slipped on the wet deck in a heavy seaway and fell, striking his left knee, he thought, against a steam-pipe. He said that he had a good deal of pain at the time but was able to get up and limp slowly along the deck. He did not come to me nor send for me till the next day, when he came to the dispensary and gave me the above history. His complaint was that "he could not straighten his knee." He did *not* complain of pain. On examining him, I found that there was a moderate degree of swelling over the front of the knee-joint; the swelling was not tense, but was tender, though only slightly. The tubercle of the tibia was uninjured. The patella was also apparently uninjured, but was very high up. It was freely moveable and movement did not cause pain. Below it there was a gap, which was partly filled up by the swelling over the front of the joint. He was absolutely unable to extend the leg. I made a diagnosis of rupture of the ligamentum patellæ and put up the limb on a posterior splint, with downward traction on the patella and a firm bandage over the joint. On our arrival at Valparaiso on June 26th I sent him ashore to the Hospital San Juan de Dios, where he was under the care of Dr. Page. On June 30th Dr. Page operated, turning up a flap in front of the joint. The ligamentum patellæ was found to be almost completely torn across, only a few fibres remaining undivided, and these showed evidences of having been stretched. The torn ends were approximated by strong chromicised catgut sutures, and the limb was put up in the extended position on a posterior splint. Unfortunately, I am not able to give any particulars of the result of the operation, as the wound had not been dressed by the time we sailed from Valparaiso, and I have not yet heard that the patient has returned to England. If it will be of interest to your readers, however, I will be glad to communicate the result as soon as I learn what it is.

I regarded the rupture of the ligamentum patellæ as being due to the sudden, *forcible* contraction of the quadriceps extensor and not to a blow from the steam-pipe. This opinion was shared by Dr. Page and Dr. J. C. Atkinson, as at the operation there were no evidences of bruising of the skin.—I am, Sir, yours faithfully,

South Shields, Sept. 27th, 1908. A. H. MACCOLL ROBERTSON.

MEDICAL DEFENCE UNIONS.

To the Editor of THE LANCET.

SIR,—In reply to the letter of "Practitioner" published in your issue dated Sept. 26th may I be allowed to state that there is one Medical Defence Union in England, of which I am general secretary, with offices at 4, Trafalgar-square, W.C., and that I shall be pleased if he will communicate with me and I will forward him full particulars. There is also the "London and Counties Medical Protection Society," Dr. Hugh Woods secretary, doing similar work, the office of which company is in Craven-street, Strand.

In respect to insurance offices covering similar ground I

Glenny, Elliott Thornton, M.B., B.S. Lond., L.R.C.P., M.R.C.S., has been appointed Medical Officer to the Ashley Down (Muller's) Orphanage Home, Bristol.

Hanson, Alfred, M.R.C.S., L.R.C.P. Edin., has been appointed a Medical Inspector of Schools for Swansea.

Swanson.—Died at Alexandria, Egypt, of typhoid fever, on Sept. 25th, in his twenty-ninth year, George Isles Swanson, second son of Dr. Swanson, York.

N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

recognition of the disease and for the present at least it was entirely surgical.

Dr. GIRARD (Geneva) discussed the Pathogenesis of Cancer, pointing out that it was very frequently seen in some countries, less commonly in others. The statistics of mortality in Switzerland (about 4000 cases a year) led him to think that there was the possibility of a connexion between cancer and alterations in the function of the thyroid. Where goitre was rare, as in the Jura, carcinoma was rare and *vice versâ*. Dr. Girard said that he had examined 2000 patients above the age of 30 years suffering from different diseases to discover whether or not they had goitre. The proportion of patients with goitre and cancer was more than twice as great as those who had cancer and no goitre. Tuberculosis, on the other hand, was rare in connexion with goitre.

Professor VON BONSDORFF (Helsingfors) reported on the Treatment of Cancer of the Lips, advocating the most radical measures for removal of the disease at the earliest opportunity.—Dr. MORESTIN (Paris), Dr. JOSÉ RIBEIRA Y SANS (Madrid), and Professor DOLLINGER (Budapest) took part in the discussion on Professor von Bonsdorff's paper.

Dr. J. COLLINS WARREN presented an analysis of 172 cases of Cancer of the Mouth and Tongue which had been treated at the Massachusetts General Hospital. He stated his belief that cancer of the mouth and tongue was a local disease limited to the tissues immediately surrounding the point of origin and to the neighbouring lymphatic system. The modern operative treatment involved the preliminary treatment of the cavity of the mouth, protection of the respiratory tract, removal of the primary lesion with at least a margin of one inch of healthy tissue, and thorough dissection of the lymphatic-bearing tissues of the anterior cervical triangle on one or both sides as a routine method of procedure.

Dr. GLUCK (Berlin) discussed the Treatment of Cancer of the Nasal Fossæ, Pharynx, and Larynx. He advocated suture of the divided trachea to the skin of the neck in cases of total laryngectomy and laryngoplasty when only a portion of the larynx was removed, whilst in all other operations where the larynx was untouched "Rose's position" with temporary compression of the wound was sufficient to protect the lungs against the danger of inhalation pneumonia. Laryngectomy he performed in a single operation, and the most radical methods were deemed to be the best. Dr. Glück showed three patients who had undergone the operation of laryngectomy and demonstrated his "rubber-funnel" apparatus as well as the artificial larynx which he employed after extensive operations. The patients shown spoke well and so audibly that one could be heard throughout the large meeting room which had not very good acoustic properties.—Mr. H. T. BUTLIN (London), Dr. DURAND (Lyons), and Dr. MORESTIN took part in the discussion.

Mr. BUTLIN presented two valuable papers—the first on the Results of Operations for Carcinoma of the Tongue, with an Analysis of 197 Cases; the second on the Results of Operations for Cancer of the Larynx, with an Analysis of 37 Cases. In each case he laid especial stress on the necessity for the routine removal of the lymphatic glands in the neighbourhood of the cancerous organ even before the glands were obviously enlarged.

Mr. HENRY MORRIS's paper upon the Treatment of Inoperable Cancer, which was read at this meeting, is published at length in our columns this week (p. 997).

Surgery of the Liver.

The second morning of the Congress was devoted to a discussion of the Surgery of the Liver under the broad headings of Gall-stones, Inflammations, including Cirrhosis and Abscess, Angiocholitis and Tumours.

Dr. HANS KEHR (Halberstadt) introduced the discussion on gall-stones in a lengthy paper containing much valuable material. He suggested that the points to be discussed should be: (1) In what cases of cholelithiasis was an operation indicated? (2) Which was the preferable operation when there were stones in the gall-bladder? and (3) In stones in the common bile-duct should choledochotomy with suture or drainage of the hepatic duct be performed? The answers which he supplied were as follows. The early operation for cholelithiasis recommended by Riedel was not advisable, but in acute and chronic empyema of the gall-bladder and in chronic obstruction of the common bile-duct an operation must be performed. When severe and continuous biliary colic was present an operation was needed if the pain interfered with the patient's work. For stones in the gall-bladder cholecystendysis was not good, cholecystostomy was rarely suitable, and the best operation was cholecystectomy. When there was a calculus in the gall-bladder Dr. Kehr preferred choledochotomy with subsequent drainage to choledochotomy with immediate suture. As to the results which he obtained, where no complication existed the death-rate was only 2·3 per cent.; when at the same time an operation needed to be performed on the stomach, intestine, liver, or pancreas, the mortality might be as great as 20 per cent.; while if malignant disease was present it might be even 75 per cent.

Mr. B. G. A. MOYNIHAN (Leeds) stated that he differed from many of the observations of Dr. Kehr. He preferred to open the gall-bladder rather than to remove it, and to make a small incision through the abdominal walls rather than a flap. It was better not to use gauze. The necessity for large operations was reduced to a minimum when due attention was paid to diagnosis in the early stages. Hitherto patients had been allowed to suffer until serious pathological disorganisation had taken place before they were brought to the surgeon for treatment.

The discussion was continued by Dr. BAKÈS (Trebitsch, Moravia), Professor HARTMANN (Paris), Dr. FINK (Carlsbad), and Professor STEINTHAL (Stuttgart).—Dr. BAKÈS explained an extensive plastic operation in which he performed a choledocho-jejunostomy and demonstrated a special form of cystoscope for use in operations on the gall-bladder.—Professor STEINTHAL agreed with Mr. Moynihan in preferring incision of the gall-bladder to its removal in the more simple cases.

Dr. PEUGNIEZ (Amiens) agreed that splenectomy or other interference with the splenic functions was sometimes useful in cases of cirrhosis of the liver and gave an account of cases in which he had obtained successful results.

Professor C. F. A. KOCH (Groningen) contributed an important paper on the Surgical Treatment of Cirrhosis of the Liver. He discussed the subject carefully and he came to the conclusions that Talma's operation—the suturing of the omentum to the anterior abdominal wall—was capable of leading to the recovery of atrophic hepatic cirrhosis, and that the earlier the operation was done the better, for in advanced cases it was dangerous. The operation was successful in about 30 per cent. of the cases, though probably the hepatic disease was not modified by the operation. When fixation of the omentum failed splenopexy might sometimes succeed. In hypertrophic cirrhosis drainage of the gall-bladder was recommended.

SOME DISCURSIVE REMARKS ON THE REARING OF CHILDREN IN LONDON.

(BY A SPECIAL CORRESPONDENT.)

II.[1]

NO PROVISION YET IN STEPNEY.—LIFE IN ROTHERHITHE.—THE BABIES' INSTITUTE.—HOUSING OF THE POOR IN ROTHERHITHE.

THE schools for mothers in Chelsea and St. Pancras are the only ones that are actually associated in a systematic way with arrangements for the feeding in a charitable or semi-charitable manner of pregnant or nursing females. A school for mothers has been opened recently in Fulham for the purpose of instructing parents with infants in arms in the feeding, management, and clothing of their offspring. The school is an adjunct to the Fulham Day Nursery and does good work, the scope of which might be much extended if more money was forthcoming. At Rotherhithe in connexion with the Bermondsey Settlement, efforts in a similar direction are being made, and here in certain circumstances meals are given to nursing mothers. Stepney was the next district to which I paid a visit, having been told that some work of a like nature to that so usefully set going in Chelsea was in progress there. But the movement in Stepney seems still quite in the air. The borough council has declined to appoint a health visitor, and although up to last year a voluntary health visitor was at work under the supervision of for the simple reason that bacteria do not exist in the early stage of disease. Again and again bacteriological examination has yielded only a negative result, and only when the physical signs and symptoms have removed any vestige of doubt about the diagnosis has it afforded any reliable diagnostic evidence. The question naturally arises whether the skill of the bacteriologist is at fault or if the non-existence of bacteria is the true explanation. Presumably the latter solution is correct, since the bacteriologist is capable of recognising the bacteria in the later stages of disease and would be able to do so in the early stage if the bacteria were present. Every man in general practice has come across cases of doubtful diagnosis in which bacteriology has afforded only negative evidence and has probably observed that it is not until the signs and symptoms are pronounced that the detection of bacteria verifies the already made diagnosis. It is true the bacillus of diphtheria is frequently found before the diagnosis is made, but it is possible and even probable that a lack of experience in the recognition of the disease is the true explanation of the uncertainty.

---

[1] No. I. was published in THE LANCET of Sept. 26th, 1908, p. 963.

It is well known that bacteria of disease are constantly being either inhaled or swallowed without producing any evil results, and the fact is explained by the suggestion that the system is capable of resisting disease, that the soil is unsuitable, or that the conditions are unfavourable. It follows, therefore, as a fair deduction, that bacteria cannot flourish in a healthy subject, and conversely that bacteria can only develop and continue to exist in diseased surroundings. In other words, bacteria thrive on disease, live on disease, and eat up disease. Consequently, unless the disease continues to progress, the bacteria consume, remove, and cure the disease.

On these data the theory is advanced that disease first occurs (it is beside the question to explain the cause), that bacteria are a subsequent development, and that bacteria are nature's remedy to cure the disease. Any attempt, therefore, by opsonic treatment to render the bacteria more palatable to, and less capable of, resisting the phagocytes is opposed to nature. Surely this theory explains why so many diseases, irrespective of treatment and often without any treatment, get well of themselves.

I am, Sir, yours faithfully,
G. SHERMAN BIGG, F.R.C.S. Edin.

PUBLIC HEALTH AS AN OPTIONAL SUBJECT FOR THE DIPLOMA OF F.R.C.S. EDIN.

To the Editor of THE LANCET.

SIR,—Although I have no personal experience of the examination, it may be of use to your correspondent "Diploma" to know of a book entitled "Medical Questions set at the University of Edinburgh, Royal College of Physicians, Edinburgh, Royal College of Surgeons, Edinburgh, and Faculty of Physicians and Surgeons, Glasgow, for several years." 1908. Edinburgh: John Currie. Price 2*s.* Here, at p. 211 *et seq.*, he will find a number of papers set in Public Health as an optional subject for the F.R.C.S.

I am, Sir, yours faithfully,
M.D.
Sept. 26th, 1908.

THE SPREADING OF INFECTIOUS DISEASE.

AT Margate petty sessions recently Mrs. E. M. A. Norton, the wife of a hotel-keeper in Lambeth, was convicted and fined upon two summonses in consequence of having removed her child from Margate to London when she was aware that he was suffering from scarlet fever. The defendant went to Margate with members of her family, including her son, aged about three years and went into lodgings. On the next day the child became ill and was seen by a medical man, Dr. E. A. White, who, on the following morning, diagnosed scarlet fever and warned the mother that if she took the patient away from Margate, as she expressed a desire to do, she must adopt proper precautions or she would be committing an infringement of the law. The course which he suggested, that of engaging a motor-car which could afterwards be disinfected, was not acceptable on account of the expense which it would have involved, and the party, which included another child, walked to the station, the sick child being carried by his mother, entered an ordinary railway carriage without informing the company's servants that anything was wrong, and travelled to London and to their home in the ordinary way. The medical officer of health, Mr. B. Thornton, who had been duly notified by Dr. White, discovered what had been done and traced the party, with the result that the local authority took out a summons in respect of the exposing of the infectious child by carrying him through the street. The railway company took out a summons also under their by-laws for conveying him by one of their trains without informing them of his condition. The mother was fined the maximum amount upon both summonses: upon the first £5 with costs amounting to £3 5*s.*, upon the second £2 with £1 1*s.* 6*d.* costs, subject to the alternative of one month's imprisonment.

TYPISTS' NEURITIS.

To the Editor of THE LANCET.

SIR,—I should be greatly obliged if any of your readers would favour me with any references to recent literature on the subject of neuritis affecting typists.

I am, Sir, yours faithfully,
M.R.C.S. ENG.

Medical Diary for the ensuing Week.

SOCIETIES.

ROYAL SOCIETY OF MEDICINE, 20, Hanover-square W.

TUESDAY.

THERAPEUTICAL AND PHARMACOLOGICAL SECTION (Hon. Secretaries—J. Gray Duncanson, H. S. Cameron): at 4.30 P.M. (N.B. The meetings of this section now take place at 20, Hanover-square.)

Paper:

Prof. Nestor Tirard: The British Pharmacopœia, its Scope and Object.

THURSDAY.

OBSTETRICAL AND GYNÆCOLOGICAL SECTION (Hon. Secretaries—H. Beckett-Overy, W. J. Gow): at 7.45 P.M.

Papers:

Dr. J. E. Spicer: Dystocia due to Distension of the Urinary Bladder of the Fœtus, with Remarks on Renal Secretion in Utero.

Mr. Alban Doran and Dr. Cuthbert Lockyer: Two Cases of Uterine Fibroids showing Peritheliomatous Changes.

Specimens:

Dr. A. H. N. Lewers: Carcinoma of the Body of the Uterus—Vaginal Hysterectomy 15 years ago—Patient free from Recurrence.

Mrs. Scharlieb, M.D.: (1) Cancer of the Fundus Uteri associated with Malignant Disease of the Small Intestine; (2) A Broad Ligament Cyst with Twisted Pedicle; (3) A Fibroid Tumour of the Ovary.

Dr. T. W. Eden: Sarcomatous Metaplasia of an Interstitial Fibroid Tumour.

FRIDAY.

CLINICAL SECTION (Hon. Secretaries: Raymond Johnson, H. D. Rolleston): at 8.30 P.M.

Short Paper:

Dr. F. J. Poynton: Pyuria in Pregnancy and *Pyelonephritis* in the Infant.

Cases:

Mr. W. Sampson Handley: Separation of the *Lower Epiphysis* of the Femur treated by Screwing.

Dr. Stanley Green: Gastrostaxis with Gangrene of Two Fingers, Penile Hypospadias after Operation.

Dr. H. A. Lediard: Subsequent Report on a Case of supposed Multiple Sarcoma of the Skin.

(And other Cases not yet notified.)

(*The patients will be in attendance at 8 p.m.*)

N.B.—Fellows of the Society are entitled to attend and to speak at all Meetings.

NORTH LONDON MEDICAL AND CHIRURGICAL SOCIETY, Board Room of the Great Northern Central Hospital, Holloway-road, N.

THURSDAY.—9 P.M., Mr. S. Paget: Vivisection and its Present Relations to Medical and Surgical Science.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC, 22, Chenies-street, W.C.

MONDAY.—4 P.M., Dr. A. Whitfield: Clinique (Skin). 5.15 P.M., Lecture:—Mr. P. Daniel: The Treatment of Surgical Tuberculosis by Iodoform, Glycerine, and Bier's Congestion Method.

TUESDAY.—4 P.M., Dr. H. Campbell: Clinique (Medical) 5.15 P.M., Lecture:—Mr. A. H. Cheatle: The Surgical Anatomy of the Temporal Bone (with lantern slides).

WEDNESDAY.—4 P.M., Mr. P. J. Freyer: Clinique (Surgical). 5.15 P.M., Lecture: Mr. A. H. Cheatle: The Surgical Anatomy of the Temporal Bone (with lantern slides).

THURSDAY.—4 P.M., Mr. Hutchinson: Clinique (Surgical). 5.15 P.M., Lecture:—Mr. S. Mayou: Ophthalmia Neonatorum.

FRIDAY.—4 P.M., Mr. S. Stephenson: Clinique (Eye).

POST-GRADUATE COLLEGE, West London Hospital, Hammersmith-road, W.

MONDAY.—2 P.M., Medical and Surgical Clinics. X Rays. Mr. Dunn: Diseases of the Eyes. 2.30 P.M., Operations.

TUESDAY.—10 A.M., Dr. Moullin: Gynæcological Operations. 2 P.M., Medical and Surgical Clinics. X Rays. Dr. Davis: Diseases of the Throat, Nose, and Ear. 2.30 P.M., Operations. Dr. Abraham: Diseases of the Skin.

WEDNESDAY.—10 A.M., Dr. Saunders: Diseases of Children. Dr. Davis: Diseases of the Throat, Nose, and Ear. 2 P.M., Medical and Surgical Clinics. X Rays. Dr. Scott: Diseases of the Eyes. 2.30 P.M., Operations. Dr. Robinson: Diseases of Women.

THURSDAY.—2 P.M., Medical and Surgical Clinics. X Rays. Mr. Dunn: Diseases of the Eyes. 2.30 P.M., Operations.

FRIDAY.—10 A.M., Dr. Moullin: Gynæcological Operations. 2 P.M., Medical and Surgical Clinics. X Rays. Dr. Davis. Diseases of the Throat, Nose, and Ear. 2.30 P.M., Operations. Dr. Abraham: Diseases of the Skin.

SATURDAY.—10 A.M., Dr. Saunders: Diseases of Children. Dr. Davis: Diseases of the Throat, Nose, and Ear. 2 P.M., Medical and Surgical Clinics. X Rays. Dr. Scott: Diseases of the Eyes. 2.30 P.M., Operations. Dr. Robinson: Diseases of Women.

and at a comparatively small outlay of money, for these poor people by some systematic scheme of visitation, but, of course, no schools for mothers could ever work results to counteract the evils of such housing and terrible poverty. Perhaps it is due to the hopeless feeling that to feed a few poor pregnant women would mean so little in the presence of so much misery that no steps in this direction either have been taken. By way of contrast, I was taken to inspect two blocks of model dwellings, one built by county council and the other by municipal enterprise. The Rotherhithe buildings are good specimens of model dwellings of the usual type. Dr. Richmond informed me of a quite interesting fact—that the infant mortality under one year of age is higher in the model dwelling than in ordinary houses. He accounted for it thus, that in the model dwellings the food has to be kept inside the house, while in the houses there is often some sort of a back yard where it is possible to store food in something like a reasonable manner.

THE INTERNATIONAL CONGRESS ON TUBERCULOSIS AT WASHINGTON.

(FROM OUR SPECIAL SANITARY COMMISSIONER.)

In Search of a Programme.—Stringent Legislation against Tuberculosis in the State of New York.—The Energetic and Successful Propaganda against Tuberculosis.—Exhibitions, Lectures, and the Growth of Local Organisations.

New York, Sept. 15th.

FOR the moment it would seem as if the whereabouts of the Congress are somewhat uncertain. Though this is to be the Washington Congress, at present the chief centre for information is in New York and the proceedings are to commence next week at *Philadelphia!* It will work out satisfactorily in the long run there is no doubt, though at present all the tickets and badges and much of the correspondence are not at Washington but at New York. Therefore on landing the best thing to do was to seek out Dr. Linsly R. Williams, chairman of the New York entertainment committee, at the offices of the National Association for the Study and Prevention of Tuberculosis situated in a huge beehive known as 105, East Twenty-second-street. The particular cell of the hive in question that interests the Congress bears the number 515, showing how numerous are the bees and cells in this hive. Here I called a few days ago and was most courteously received, then a bronze badge was conferred on me and I was told that none of the programmes were ready except a small handbill just received from Philadelphia. This announces a business meeting at 2 P.M. on Sept. 24th. On the following day at the Horticultural Hall there will be lectures that promise to be interesting and a closing meeting is fixed for Saturday afternoon. After that presumably the members are to proceed to Washington and to devote the week from Sept. 28th to Oct. 4th to discussing the real business of the Congress. No programme indicates as yet what is to be done or what will happen at Baltimore and at Boston, which towns are also to be visited. But yesterday afternoon the one and only copy of the New York programme was triumphantly brought to the above-mentioned office; and I think I was the very first person, with the exception of the organisers, to see this precious, and at that time unique, document. I hasten to transcribe its contents. At the entrance of the celebrated sky-scraper, the "Flat Iron," as it is called, we are to meet at 9 A.M. on Thursday, Oct. 8th, and be shown some of the town buildings. In the city hall the Mayor of New York will welcome the Congress. Then boats are to take the members to visit the quarantine station and the Sea-breeze Hospital for surgical tuberculosis in children. This latter is the first institution of the sort established in the United States. In the evening there will be numerous private dinner parties given to members and a lecture at the Academy of Medicine on Tuberculosis of the Heart and Blood-vessels by Dr. Martinez Vargas. On Friday the members are to visit the Ellis Island Immigration Station, the Bellevue Hospital, the Tuberculosis Boat, the Rockefeller Institute, and other places, ending in the evening at the Hippodrome. On the 10th there will be an all-day trip to the Loomis Sanatorium at Liberty and trips to other comparatively distant sanatoriums. After this the Congress and its excursions conclude. It is very unfortunate that all this could not have been arranged at least three months ago, or better still, some six months ago, so that the different countries might have been able to send information as to the persons who would be likely to participate in these various trips.

There is no doubt that much interest will be felt in regard to what so enterprising a country as America has been able to do in the great struggle against tuberculosis. The programme prepared for the members of the Congress when at New York will in any case afford them opportunity of judging what has been done and planned for the State of New York. The population of that State is about 8,000,000, and, counting municipal institutions and private charities, and paying and free sanatoriums, there are in all 3556 beds available for the treatment of tuberculosis in sanatoriums or special hospitals. This number will be greatly increased in a few years by the action that has now been taken by the local authorities. The New York State last year passed a very stringent Anti-tuberculosis Law and the State Board of Health has power to see that various enactments are really carried out by all the small local governing bodies.

As an example of the stringency of this new law, it may be mentioned that the notification even of incipient cases of tuberculosis is rendered obligatory. This has to be done by the attendant medical practitioner, but the records must be kept strictly private and are therefore not open to general inspection. When a patient leaves his dwelling it must be disinfected before it can be re-occupied. This also must be done within 24 hours. Persons with tuberculosis who spit in public places may be fined £2. Physicians who fail to report cases shall be deemed guilty of a misdemeanour and fined not more than £20 and not less than £1. Some fears are entertained that public opinion is not yet ripe for such a law. The State of New Jersey has a law fining medical men £10 if they fail to notify cases, and the result is that magistrates will not impose so large a penalty. Therefore, and in the hope of obtaining convictions, the New York law makes the penalty as low as £1.

There is, I am assured, a very great progress in public opinion on these questions. The sanitary reformers were agreeably surprised by the facility with which the New York legislature adopted the new Anti-tuberculosis Law. The fact is that the National Association for the Study and Prevention of Tuberculosis has been very active and has brought great pressure to bear on public opinion during the last few years. It has worked hard to obtain the support of the press and this has often been given very readily. The greatest enterprise is the organisation of travelling exhibitions. From Toronto to Mexico these exhibitions have attracted thousands of people. Some 20 of the largest cities in the United States have thus been visited. Remaining two or three weeks in each town the exhibition supplies a great deal of matter to the local press. Then there are posters on the walls, and handbills and literature distributed on all sides, together with a series of lectures. All this is done in a manner likely to attract the poorest people. No technical terms are used, but everything is contrived so as to attract and to interest the general mass of the population. This was started without any money but it brought in money and many gifts. Then another very important result is that when these exhibitions are held in towns they generally end by bringing about the foundation of a local branch of the National Association. These local branches have become in many instances strong enough to finance their local efforts; all that they need is material—objects to exhibit—and general advice from the central organisation. Yet the holding of an exhibition means some expenditure. According to the importance of the town and of the exhibition and the amount of paid publicity given, an exhibition for the prevention of tuberculosis has cost from £60 to £400. It is calculated that at least 700,000 visitors have been attracted to these exhibitions. Sometimes the result is not only the forming of a local committee to deal with the prevention of tuberculosis but also a permanent local exhibition has been established in some towns. This is notably the case in New York, Boston, Wisconsin, Minnesota, Chicago, &c. For the moment, however, many of these local exhibitions are closed, as they have sent some of their best specimens to the great Congress Exhibition of Washington where they will remain for three weeks. Naturally such exhibitions are free. There is no attempt to make money out of them. Often the lectures are illustrated with lantern slides and

authorities and guardians to consider the best method of dealing with a disease acknowledged to be preventable and in a great measure curable. Boards of guardians, singly or in combination, could erect suitable sanatoriums, and he thought that the system of open-air treatment "had now passed the experimental stage." Workhouse hospitals had failed, the reason being that most cases came when too far advanced, but they were useful for the segregation of cases "in the last or acute stage." Dr. Garrett and Dr. Rhodes supported Mr. Macfarlane's views, and Dr. Rhodes proposed the following motion:—

> That, in the opinion of this conference, it is desirable that sanatorial accommodation for the special treatment of phthisical cases be provided by the Poor-law unions within this conference area.

He proposed another motion, also carried, for forming a subcommittee to inquire into, and to report on, the best means of providing such accommodation. Very few will consider that the various efforts made to combat pulmonary tuberculosis are unnecessary and uncalled for, but it is satisfactory to know that already the death-rate from pulmonary tuberculosis is, no doubt in consequence of better hygienic conditions, though these are still bad enough in poor districts, steadily decreasing. Dr. Rhodes stated that in Lancashire in 1835, with a population of 1,500,000, the deaths from pulmonary tuberculosis were 8124. In 1907, with a population of 5,000,000, the deaths were 6238. It was agreed generally that this movement would have to be conducted economically and that "extravagance must be sternly repressed," and it was stated that the Durham Sanatorium "cost only £86 a bed." It appears as if the country were gradually becoming alive to this question of dealing with pulmonary tuberculosis, and it is a national not a local question.

Suicide and Suggestion.

A verdict of suicide during insanity was returned yesterday, in the case of a clerk who had lost his situation through drink and poisoned himself with gas. The city coroner pointed out that suicides by gas poisoning were on the increase. Three had occurred within a week and "he could not help thinking that some sort of suggestion was going on." Whether due to harmful literature, describing how it could be accomplished by gas, or whether it was through details being given in the daily press he did not know; but "he thought he was justified in asking the press on this occasion to keep out the details of the case." He thought if this were done the "epidemic" would probably cease. There is no question as to the wisdom of this suggestion and in this instance the local papers seem very properly to have acted up to it.

Death from Fear.

An inquest held on Sept. 24th at Morley on a man, aged 26 years, seems to show that death was due to fear rather than to anything else. Four teeth had been extracted by a dentist without "gas," as the patient was very nervous about taking it. An ordinary amount of bleeding took place but it set in later and the patient went to Dr. A. Firth who stopped it. It recurred, however, and Dr. Firth went to the man's home and stopped it again. The man was very nervous and fancied that he was going to bleed to death. He became delirious and died from exhaustion and heart failure. It was stated at the inquest that death was in no way due to the dental operation. The verdict was "Death through exhaustion from acute mania due to nervous fright." It is a question whether the education and bringing-up of these days may be to some extent accountable for the hypersensitiveness and want of "pluck" that are too common.

Medical Work in Schools.

At a meeting of the Manchester education committee held on Sept. 21st a scheme for the medical inspection of school children was adopted for submission to the city council and the Board of Education. Under this scheme Dr. A. Brown Ritchie will be the school medical officer for Manchester. There will be in addition three assistants to him at commencing salaries of £250 per annum, rising by four annual increments of £25 to £350 per annum, with £10 a year in each case for travelling expenses. The question of the appointment of medical women is to be postponed for the present. Dr. J. T. D'Ewart's services are to be retained on the present terms. The city is to be divided into three districts, each with an assistant medical officer. Five nurses are to be appointed and 12 weighing machines are to be bought for use in the schools. One of the lady members of the committee (Miss Burstall) was surprised that it was not proposed to appoint "at least one medical woman," and moved an amendment that of the three medical officers at least one should be a woman. This was seconded by a gentleman, not so much from sympathy with lady doctors as from sympathy with lady teachers and scholars. The chairman, Sir Thomas Shann, said that the matter had been fully discussed and that it would be very unwise at the present to act otherwise than in accordance with their recommendation. He said that next year the number of medical officers would have to be increased "and then would be the time to consider the appointment of a woman," thus displaying no great enthusiasm for the women doctors. Vice-Chancellor Hopkinson was in favour of so altering the wording of the scheme that it might be left to the discretion of the committee to appoint a lady doctor if it were felt desirable. Sir Thomas Shann replied, however, that the committee had decided, on very good grounds, to appoint medical men only at first. In the end Miss Burstall withdrew her amendment, having drawn attention to the matter. So the dispute, if it be one, will come up again.

(FROM OUR OWN CORRESPONDENT.)

The Need for Further Facilities for Post-Graduate Study.

NOW that the vacation is over and the work of a new educational year is about to begin attention may well be called to the substance of an address given by Dr. A. E. Morison to the members of the North of England branch of the British Medical Association on the occasion of his assuming the office of president of the branch in June last. Dr. Morison recognises the great value of the work of the Association in organising the profession and urges that its energies should now be employed in another at least equally important direction—namely, the provision of facilities for post-graduate study. In Dr. Morison's opinion the local branch of the Association should be a centre of post-graduate education. He argues that learning is already highly specialised and is tending day by day to become even more so. This being so, it is impossible for one man to be at once "a skilled pathologist, physician, obstetrician, operating surgeon, and all-round specialist," but it is nevertheless a crying need that the practitioner engaged in the everyday practice of medicine should be provided with the opportunities necessary for informing himself of the advances made in the various branches of his art and science. The general practitioner does not ask to be provided with the facilities for becoming an all-round specialist but merely to be taught when the specialist can help him and what he can do for him. In Dr. Morison's words, "It is essential to the maintenance of our position for us to know when blood examinations, bacteriological investigations, Roentgen ray pictures, and examination with all the special instruments are necessary and advisable and when surgical operations are required." He continues, "In Newcastle there is, if properly organised, a collection of cases and material which ought to attract not only practitioners from our own area but from all parts of England. It only requires that the matter be fairly taken up by this branch to insure its success." No one will deny the truth of these contentions. Of the desirability of post-graduate study there can, of course, be no question; it is practically a necessity. The material is to be found in abundance in this city and the opportunities are present if they were utilised. Dr. Morison states that if the matter were fairly taken up its success would be insured. As regards this point I may say that the excellent attendances on such occasions as the all-day scientific meetings and at the classes which are at present held are sufficient evidence that Dr. Morison's contention is justifiable. The suggestion put forward in this address on behalf of the great body of general practitioners by their present representative should, and indeed must, receive most careful attention. The importance of the matter and the fact that the address was given during holiday times constitute the reason for referring to the subject on the present occasion.

College of Medicine.

The winter session begins on Oct. 1st. The College calendar for the ensuing year has just been issued. As

Communications, Letters, &c., have been received from—

conditions revealed by medical inspection of the school children of the town. Much, he says, may be done without any specific medical treatment. For example, a certain proportion of the eye defects are due to defective lighting of class-rooms, to badly constructed desks, or to improper and constrained positions in writing and reading, while many of the disorders of the throat and nose can be remedied by improved conditions of heating and ventilation in the rooms. In the event of the education authority formulating any scheme for the medical treatment of the children attending the elementary schools Dr. Walford considers that it should be made to apply to that class of children whose parents are too poor to pay for medical attendance and are yet not eligible for the Poor-law relief.

(FROM OUR OWN CORRESPONDENTS.)

Final Examination at the University of Glasgow.

OWING to the recent changes that have been made in the medical examinations at the University of Glasgow there will be the unprecedented number of three finals in 12 months—namely, in December, 1908, and in April and October, 1909. When it was first arranged to have two finals in the year the dates fixed were December and June, but this has now been altered to April and October. This latter change will benefit graduates in a way that is not at first apparent. Formerly when the final was held in June the graduation did not take place till the middle of July, whereas in other Universities, Edinburgh for instance, the final examinations were over about three weeks earlier, the result being that all the best posts in the country at the time were taken up before the Glasgow students were qualified to apply.

The Crichton Asylum, Dumfries.

In a recent article in the *Glasgow Herald* attention was drawn to the circumstances which led to the establishment of the Crichton Asylum. In 1823 there died at Friars' Carse, near Dumfries, Dr. James Crichton. He was a native of Sanquhar, studied medicine, became physician to the Governor-General of India, and amassed a large fortune by commercial enterprise and medical practice. On his death he left the sum of £100,000 to his widow, Elizabeth Grierson, the great-grand-daughter of Sir Robert Grierson of Lag, to be used for such purposes as she and trustees might direct. They were inclined to the establishment of a University at Dumfries, but a series of difficulties arose. Lord Brougham was Lord Chancellor at that time and he intimated that a scheme for the establishment of a fifth University in Scotland would meet with his opposition. The scheme was thereupon abandoned, and after consideration Mrs. Crichton decided to apply her husband's fortune to the erection and endowment of an institution for the treatment of the mentally afflicted. At that time in Dumfries the provision for persons mentally weak was notoriously inadequate and unsatisfactory. 12 apartments in the Dumfries Infirmary were kept for the detention of such patients, and this accommodation proving insufficient it was supplemented by the use of prison cells. In 1835 the foundation-stone of the Crichton Royal Institution was laid and a building was erected at a cost of £50,000 with accommodation for 120 patients.

"Home for Incurables" for Elgin.

Under the will of the late Mr. John Munro, merchant, the town of Elgin has benefited considerably. Amongst other legacies the sum of £6000 is left to the provost, magistrates, and town councillors of Elgin for the erection, equipment, and carrying on of public baths and a similar sum for a like purpose to the town of Forres. On the death of his sister his trustees are directed to convert his dwelling house, with garden and offices, into a home for persons, drawn from the county of Elgin and its burghs, suffering from diseases usually reckoned to be of an incurable nature. It is also directed that the whole residue of the estate shall be held as an endowment for the home.

Aberdeen City Hospital: Proposed Additions.

Extensive additions to the Aberdeen City Hospital are contemplated by the public health committee of the Aberdeen town council. The additions consist of (1) the enlargement of the two outside pavilions, Nos. 1 and 4, towards Urquhart-road, by 17 beds each and rearranging the two old wards to suit the new pavilions; (2) erecting an additional pavilion to contain 16 beds, at the south side of the offices; (3) erecting a skin disease pavilion, to contain 12 beds; (4) providing additional nurses' accommodation in the administration block by heightening the original front block to the south and making it three floors high, which would provide ten single bedrooms and two double bedrooms for nurses in addition to the present accommodation, and also provide a nurses' recreation room over the kitchen wing on the same floor; and (5) enlarging the reception block by additional wings to the south and north ends of the same, and rearranging the present internal wards to suit the new additions, giving accommodation for 12 beds extra. Pavilion No. 4 would be specially constructed for cases of pulmonary tuberculosis. At the present time there is accommodation in the hospital for 127 patients, and if the whole of the proposed additions were carried out it would be increased by 74 beds, making in all room for 201 patients. The estimated cost of the additions is £12,500, and if the scheme is approved the work will be commenced at once in order to give work to the unemployed.

Death of Sir Arthur Vernon Macan.

THE death of Sir Arthur Vernon Macan, professor of obstetrics in Trinity College, Dublin, took place on Saturday last, Sept. 26th, at his residence, 53, Merrion-square, thus depriving Dublin of one of its most prominent practitioners.

Richmond Hospital and Pauper Lunatics.

The question of pauper lunatics was before the meeting of the guardians in the North Dublin union workhouse on Sept. 23rd, to which reference was made in THE LANCET last week. A letter was read from Mr. J. O'Conor Donelan, medical superintendent of the Richmond and Portrane lunatic asylums, calling attention to the crowded condition of those institutions and stating that he had been directed by the joint committee to request that the milder or purely senile cases should be retained in the workhouse until such time as adequate provision should be made for the feeble-minded, as distinguished from the strictly insane. Early legislation on the matter has been promised, but meanwhile the joint committee finds that all the available accommodation in its two institutions has been practically absorbed. A scheme of further extensions is at present being developed, but no additional relief can be hoped for within the next 12 months. The chairman observed that no more could be done than there had been in the circumstances. They were pressed on the one hand by the joint committee not to send these people to its institutions, while, on the other hand, the Local Government Board was pressing to have them sent out of the workhouse. One member pointed out that they could not be left to die in the streets, and another having suggested that it was a matter that might be referred to the committee which was at present dealing with the general management of the house, an order was made to that effect. On the same date a corresponding discussion was carried out at a meeting of the guardians of the South Dublin union, at which it was decided that the guardians would not recede from their right to send insane paupers to the asylum.

Coombe Hospital, Dublin, and the Boarding-out of Infants.

At a meeting of the Rathdown board of guardians on Sept. 23rd some of the items of recent practice of the Coombe Hospital received a share of censorious criticism. Miss Griffin, inspector under the Infant Life Protection Act, reported the death of an infant named Alice Clarke, at the age of three weeks. She had been taken out to nurse by a Mrs. Mahon of Dundrum on August 31st. The nurse stated that she had received no certificate of health respecting this child nor any instructions or advice from the hospital authorities as to care or diet. After death there was a post-mortem examination and an inquest and the jury found that

and now another unwelcome visitor of Asiatic origin has come to accelerate its "measures of precaution." On the morning of Sept. 18th in the offing of Trieste the pilot of the steamship *Francesco Ferdinando* fell ill with symptoms believed to be those of plague and died. Another of the *personnel* of the same vessel, seized with precisely the same symptoms, was conveyed to the hospital. In the two cases clinical investigation left no doubt that the cause of illness and (in the former) of death was pestis bubonica due to the presence of rats in the ship, several of these rodents having been found dead on board. The steamer had arrived from Bombay on August 21st, putting in at Fiume on Sept. 12th and thereafter re-entering the offing of Trieste on the 17th. As soon as the official examination had certified the nature of the disease the local authority took the required steps towards limiting its spread. So much for the plague. As to cholera, the Riviera Ponente and the Riviera Levante of the Mediterranean littoral, frequented as both are by Russians, are now, by the combined action of the French and Italian Board of Hygiene, subjected to the most stringent precautionary measures. On Sept. 21st the Prefect of Nice, accompanied by Dr. Castelli, director of the "Sanità Pubblica," and Dr. Anger, inspector of the French custom house, proceeded to enforce those measures at the sanitary station established at Ventimiglia.

Wounds from Poisoned Arrows in the Benadir.

In the encounters with the natives in this the most recently acquired of Italy's African possessions, certain of the Ascars (coloured troops) were wounded by arrows, but—slight as the lesions were—they died in spite of surgical treatment as prompt as it was careful. The medical staff, suspecting that the non-response to measures usually effective in such cases was due to exceptional causes, has, with the consent and coöperation of General Di Giorgi, chief in command of the expeditionary force, sent to the military hospital on the Caelian Hill some specimens of the arrows used by the natives, together with the "materiale clinico" necessary for the purposes of investigation, chemical and bacteriological. The arrows were collected on the scene of the two encounters of July 11th and 12th last in the Mellet woodland where Lieutenant Lombardi and certain of the coloured troops met their death. Pending the conclusions of the Roman commission to be issued in a special report, it is believed that the suspected poison is either curare or "ubaina" (glucoside of a plant common in the wooded country of the Benadir—the so-called "ubai"—two milligrammes of which suffice to *fulminare* (kill outright) a dog). When issued, the report of the commission will be distributed among the medical *personnel*, combatant and lay, of the Benadir Colony, who, in the meantime, seem to have convinced themselves that in wounds inflicted by the arrows in question the hypodermic injection of strychnine is not without real benefit.

More "Monstra Natantia" in the Mediterranean.

The shark on the prowl has long been a recognised danger in the Adriatic, particularly at the bathing establishments on its littoral, but now the Mediterranean itself is threatened with the same formidable aggressors. On Sept. 19th, off the Riviera Ponente, an enormous "pescicane" had been sighted in the near neighbourhood of more than one sea-bathing resort, deterring the more intrepid swimmers from venturing far out from shore and, indeed, spreading something like a scare among all and sundry. The owners of a fishing smack employed in netting tunny, having found some difficulty in landing their "take," at length ascertained that they had captured more than they bargained for—a shark of colossal proportions. They succeeded in noosing it and taking it in tow by means of a strong cable, and in spite of its furious efforts to escape at length landed it not far from Niellon, where, with knife and bayonet supplied from the fort, they gave it the *coup de grâce*. It proved in point of size worthy of a place in the museum, being not less than eight metres in length and 1500 kilogrammes in weight. The head was one metre long, while its teeth, triangular in shape, resembled those of a powerful saw, and were from eight to ten centimetres in length. On being eviscerated it was found to have swallowed a tunny weighing 30 kilogrammes and a small shark weighing 25 kilogrammes. Fortunately no trace of a human victim was found in its capacious interior.

Sept. [illegible]

VIENNA.

(FROM OUR OWN CORRESPONDENT.)

Experiments with Marmorek's Serum.

IN a paper communicated to the *Wiener Klinische Wochenschrift* Dr. Grüner has published the results of his clinical observations on the serum of Marmorek in a series of cases of tuberculous diseases of children. He used subcutaneous injections of the serum strictly in accordance with Dr. Marmorek's instructions, the only cases taken into consideration being cases of tuberculosis affecting the bones, the lungs, and the meninges. The series included 44 children, all of whom were observed clinically; 12 of them were suffering from tuberculous meningitis. The investigations were carried out at the special desire of Dr. Marmorek. The method employed was as follows. A lumbar puncture was made, from 10 to 20 cubic centimetres of cerebro-spinal fluid were removed, and the same quantity of the serum was injected immediately afterwards. The treatment was ineffective in averting the customary fatal course of the disease, the nature of which was confirmed in all of the cases of meningitis by the post-mortem examination. As regards the treatment of the other cases the serum was sometimes injected per rectum, but as a rule this method was not adopted. The quantities used were from *two to five* cubic centimetres given every third or fifth day; in the cases of meningitis the subdural injections were of 10 to 20 cubic centimetres, whilst at the same time 100 cubic centimetres were injected hypodermically. Of the whole series only one case was arrested (a case of infiltration of the left apex), five were improved, nine became worse during treatment, and the remainder remained unaffected in either direction. In order to test the efficacy of the serum old tuberculin was mixed with the 100,000-fold quantity of Marmorek's serum and with this mixture cutaneous vaccinations were made, whilst control vaccinations with tuberculin mixed with normal horse serum were also made. Both series of vaccinations proved that the admixture of Marmorek's serum with tuberculin made no difference to the cutaneous effect of that substance when it was injected. Dr. Grüner draws the following conclusions. Marmorek's serum has no trustworthy effect in surgical or internal tuberculosis. Even in long-continued use with large doses (in some cases up to 300 cubic centimetres were employed within six months) the serum cannot prevent the appearance of fresh foci or new forms of the disease. In some cases it decidedly accelerated the course of the disease. There is no principal difference as regards the action of the serum whether it be introduced per rectum or subcutaneously. Even in 100,000-fold quantity the serum does not lessen the cutaneous reaction to tuberculin. "Therefore Dr. Grüner concludes that Marmorek's serum cannot be regarded as possessing specific properties against tuberculous diseases. The favourable results reported from different sources must be carefully analysed before accepting them for general conclusions."

Instructions for Reducing Infant Mortality.

Following the lead of German physicians and acting on the same principles as prompted the distribution of leaflets for suppression of venereal disease,[1] the Gesellschaft der Aerzte has turned the attention of its committee for sanitary improvements to the necessity of instructing all classes of the population as to the best way of bringing up infants. Physicians, midwives, and all those coming in contact with young mothers, especially the teachers in the highest standards of the public schools, are asked to exert their influence to persuade the public that the most natural and therefore the best nourishment for babies is their mother's milk. A circulating leaflet has been prepared and will be distributed amongst the classes of the population concerned containing valuable instructions on this point. Only in cases where the mother is physically unable to nurse her child is the use of thoroughly clean milk advised. The advantage of "mixed nourishment" consisting of the mother's and of cow's milk over the latter alone is insisted upon. The results of the so-called "gouttes de lait" or Milchkassen, which provide either at a nominal cost or free of charge unobjectionable cow's milk for babies, are chilled the cordial partnership between board and staff in that successful hospital; nor was there any loss of efficiency by cross purposes or conflicting opinions.

---

[1] THE LANCET, August 1st, p. [illegible].

The next counsel I would offer is that a lively and effective sympathy be manifested with scientific aspiration and invention, even by lay managers who may be unable to perceive the purport of particular, or indeed of any researches. To speak personally, I shall never forget the almost comic astonishment of a certain weekly board to whom some 40 years ago I appealed for a very modest outfit of electrical scientific apparatus, and at a later date for means of registering surface temperatures by electrical thermocouples, of recording continuous curves of bodily temperature by watchwork, and so forth. Bit by bit I did indeed get something of what I wanted, but with a delay and tediousness that crippled my endeavours. Now, I pray you to believe that no money is better expended than small sums allotted to investigation by young men of scientific ardour whose education in method is fairly adequate. If it does little more than keep the junior staff and their pupils active and curious the outlay is well rewarded.

CLINICAL PATHOLOGY.

And thus I am led naturally on, not merely to urge in general terms the alliance of clinical medicine with scientific research, for this is a counsel not needed in Manchester, but to advocate in particular a far closer intimacy and coöperation than at present exist between the physician and the pathologist. Since a few of us, some years ago, began to urge the creation of clinical laboratories close to the doors of the wards, something no doubt has been done; but it has been done, in my opinion, awkwardly and very partially. Herein I think the medical manager, as sinning against the light, is more to blame than the lay, so that the pathologist—I speak not now of morbid anatomy which has long enjoyed every advantage, but of pathology in its dynamic aspect—the pathologist in this sense is kept aloof from the patient whose processes it is his main business to interpret; and the physician, with morbid anatomy nearer his elbow, has been losing something of the sense of disease as dynamics, which, with all their fantasies of vapour and humour, was apprehended by our ancestors of the last two or three centuries. Of late years a remarkable integration has begun, and is rapidly proceeding, between anatomy and physiology; and, if medicine is to advance as it has been advancing, the same integration must be created between static pathology, medical practice, and dynamic pathology—the pathology of processes. That the pathologist must investigate the sick man in whose body these defects and perversions are at work seems too obvious for assertion. Yet when some few months ago I asked, somewhat ironically I fear, of a distinguished pathologist in a great university if he had free access to the wards of the hospital, he replied, "If I were to set foot in the wards there would indeed be a pretty hubbub in the staff." So the pathologist, at arm's length in a laboratory down the street, working, as it were, in a balloon, and fed upon occasional crumbs from the hospital table, never sets eyes upon the concrete problems which it is his business to solve. There seems to be an opinion abroad that the pathologist, who has never approached a patient since his graduation, can by some esoteric ingenuity put together the conditions of these problems in his laboratory; or indeed under these purer conditions find more comprehensible explanations. To endeavour in the laboratory thus to reproduce problems in simpler terms is a valuable part of scientific method; but surely it is a truism that such researches, unless incessantly tested by the touchstone of nature, are apt to lead at best to conclusions as abstract as the ingenious conditions out of which they arose are artificial. In the simpler sciences, it is true, such methods go farther; a mathematician, in no way conversant with machines, may often enlighten an engineer; but even in the simplicity of mechanics the shortcomings of mere academic methods soon become conspicuous: how much more crippled then must be the academic pathologist who is denied full conversance with those infinitely more complex and multifarious machines we call plants and animals! It seems absurd to labour such a point as this, and in a university so vigorously empirical as Victoria; still as we have long ceased to be surprised at the absurdities which convention and tradition maintain even in the hardest heads, even here these counsels may be useful.

How, then, are we to abolish so fallacious a distribution of work? The physician, who in the earlier phases of scientific medicine proved himself, on the very principles just proposed, to be the ablest of pathologists, can no longer, in the vast extension of the field, devote himself fully to pathological research. It is all he can do to coördinate its discoveries with clinical practice. Moreover, the field of qualitative clinical work is filling up, and progress now depends on the far more arduous and exacting quantitative appreciations. Both physician and pathologist, each by his own methods, must work in the ward at the facts; the pathologist must have almost as free a run as the physician—almost as free, for ultimately, of course, the physician must govern all that concerns the patient's well-being—and must accordingly have a laboratory of first instance in the neighbourhood of the ward; his departmental and research laboratories will, of course, be elsewhere, yet not so far away as to estrange him from the patients. By this concert the outlook of the physician himself, his assistants and his classes, would be continually enlarged, and the attention of the pathologist as continually riveted upon those signals, criterions, contingencies, interdependencies, eccentricities, lapses, glimpses, which in the laboratory no ingenuity can forecast or reproduce, but in which the practical and empirical physician has his being and justification.

And what is true of the hospital is no less true for private practice. It is not fair to the pathologist, it is not fair to the patient, in cases, let us say, of biochemical disorder, of vaccinal therapeutics, of obscure toxic processes, and so forth, to pick the brains of the pathologist at second hand. The pathologist should be summoned to take his proper part in consultation with the family physician, and any other consultant, all upon equal terms. So far as circumstances and the old customs of private practice permit, it is my endeavour to bring this about, and, if expenses must be kept down, the medical consultant may be permitted to resign a few of his visits to the pathologist, who, by the way, is anything but a rapacious person.

OUT-PATIENTS.

Of the departments of a great hospital that which is most rudimentary, rudimentary almost to chaos; that in which the evil, which in this world attends upon the good, survives most manifestly, and is perhaps increasing; that which on many grounds is open to the censorious criticisms of medical men outside its walls and of the public, and indeed of the hospital staffs themselves, is the out-patient department. Physicians resent all that savours of quackery, at any rate in medicine; yet is there any custom more apt to engender and to foster quackery than to encourage mobs to wander round our halls for potions to be hugged to their bosoms as charms? In not a few cases, it is true, these herbs and salts have some virtue; but in how many are they not stock recipes, either wholly futile or at best impotent as auxiliaries against unwholesome habits and conditions of life which the physician, unable to ameliorate, gets weary of denouncing? Too soon he learns to say to himself, "Poor creatures, errant or sinful, God help them, I cannot; yet if pill or potion be a comfort to them, or a hope, by all means let them have it." And the quackery does not end here; unhappily it permeates upwards into higher social ranks, to the degradation of scientific therapeutics.

In respect of the out-patients, hospital abuse, by persons able to pay for advice, is perhaps exaggerated; still, by direct provision or by means of provident dispensaries, some of them might be induced to obtain the more individual and discriminating aid of physicians living among them, conversant with them and their ways, and with the external causes and conditions of their maladies. Thus, by treatment of a more comprehensive kind on physiological lines, vulgar notions of the laws of life and disease would be enlarged, and some health would be compassed not for the body only but also for mind and character.

Hitherto I have been considering the out-patients of Great Britain as hordes; but at the same time I am not forgetful of the precious gifts of diagnosis, and even of treatment, which thus fall to the lot of many of them, as to persons overtaken by acute or vexatious diseases, but who, even if fully aware of the nature of the case, are unable or unprepared to pay for medical aid. Many sufferers are thus consigned to the wards, and on discharge are kept still under supervision; others are benefited by topical remedies, specific drugs, or elaborate technical methods, such as to patients. The hospital committee entered an action for libel against Mrs. Roberts, and the case occupied several days in hearing. Judge Eagleson in summing up said that he did not believe a single word given in evidence by certain witnesses in support of the charges. He was satisfied that the defendant had no grounds for referring to the management as inhumane and that there was gross misrepresentation in calling certain rooms "cold, damp cells." There must be judgment for the plaintiffs with full damages claimed, but he thought that the defendant had made an honest mistake. The damages claimed were £49, but counsel intimated that upon Mrs. Roberts giving an expression of regret the plaintiffs would consent to a verdict for 1*s.* damages without costs. Judgment was entered accordingly.

The Melbourne Benevolent Asylum.

The fifty-eighth annual meeting of the friends and supporters of the Melbourne Benevolent Asylum was held under the presidency of the State Governor (Sir T. Gilson-Carmichael). On June 30th there were 650 inmates (404 males and 246 females). Altogether 1000 persons had been relieved during the year. The cost per head was 5*s.* 1½*d.* per week, covering medical attendance, nursing, drugs, clothing, food, fuel, light, administration, and burial expenses. The number of deaths was 179, including 58 old-age pensioners. Many were admitted in a moribund condition. There were 100 blind people amongst the inmates. The new asylum to be built at Cheltenham would cost £96,000 and the foundation stone would be laid next October.

The Contagious Diseases Act.

The Premier of New South Wales has introduced a Bill which contains a provision for detaining prisoners who may be found suffering from venereal diseases for purposes of treatment. An immediate agitation has been raised by a section of the public and the old cries of State recognition of vice and so on are being lustily proclaimed. It is improbable that the measure will be carried into effect.

Vital Statistics for Australia.

The Commonwealth statistician has published the first complete tabulation of a year's vital statistics for Australia. The figures cover the year 1907 and show that the total number of births in the Commonwealth was 110,347, which is the highest on record. The birth-rate has gradually increased since 1903 (the year of the great financial panic). In that year it was 25·23 per 1000 of the mean population and has risen to 26·55. 6075 mothers were under 21 years of age, the youngest being 14; while of mothers of illegitimates the youngest was 13. One mother in 106 gave birth to twins and 1 in 7872 to triplets. The illegitimate birth-rate was 6·15 per cent. of the total births, which is a slight decrease. 32,470 marriages were celebrated during 1907. In 12 instances both contracting parties had been through the divorce court. In one case the bridegroom was 83 years of age and the bride 79. The deaths numbered 45,305, equivalent to a rate of 10·9 per 1000 of the mean population. No fewer than one-fourth of these occurred in public institutions.

Hospital Collection.

The directors of the Royal Prince Alfred Hospital, Sydney, have adopted a somewhat novel mode of stimulating public interest in the needs of the institution. A bioscope entertainment was given in a suburban town-hall and views were shown which depicted a street accident to a blind man to whom first aid was rendered by the civil ambulance brigade which also conveyed him to the hospital. There he was shown undergoing treatment in the casualty department and afterwards as a patient in the wards, as a convalescent in the grounds, and finally as leaving the hospital cured.

Obituary.

Dr. J. R. McInerney, a well-known physician in Melbourne, died on July 24th from pneumonia after a short illness. The late Dr. McInerney was a native of Galway and after studying medicine and qualifying in Dublin eventually took the degree of M.D. Durh. He was for 25 years physician to the Melbourne Hospital but was defeated four years ago and was subsequently appointed indoor physician to the Prince Alfred Hospital.

Dangerous Prescriptions.

The Sydney city coroner recently held an inquest concerning the death of a woman who died from arsenic poisoning. The evidence showed that the deceased had suffered from rheumatism and had taken a medicine the prescription for which had been obtained by her husband from the chief mate of a steamer while on a voyage several years ago. The husband had the prescription dispensed by a Sydney druggist. After a few doses his wife became very ill and eventually died in the Prince Alfred Hospital. The Government medical officer, who made a post-mortem examination, said that in his opinion the doses of arsenic were excessive and that the prescription ought not to have been made up without the signature of a well-known medical man.

Deaths from Cocaine.

In the South Australian House of Assembly the Attorney-General, in reply to a question, said that he had been informed of two cases of death during the past few days consequent on the administration of cocaine during dental operations. The medical certificate in one case was "heart failure"; in the other "diabetes, poisoning from cocaine or eucaine, coma." The same dentist operated in both cases and he was a registered practitioner but had passed no examination in dentistry or anæsthetic administration in that State. The Attorney-General expressed surprise that the city coroner had considered no inquest necessary and he had asked his reasons for this opinion. If necessary further action was to be taken.

Sept. 3rd.

Obituary.

FREDERICK HENRY ALDERSON, M.D. ST. AND., M.R.C.S. ENG., L.M., L.S.A., J.P.

THE death occurred on Sept. 3rd of Dr. Frederick Henry Alderson at his residence, Aboukir House, Poole-road, Bournemouth. Dr. Alderson was born in 1839 and, following the footsteps of other members of his family, began the study of medicine in the then usual way, as a pupil of the late Dr. Ayling of Great Portland-street, W. Subsequently he entered the Middlesex Hospital and qualifying in 1863 M.R.C.S. Eng., L.S.A. Lond., L.M., in 1880 graduated M.D. of the University of St. Andrews. He was assistant house surgeon at the Poplar Hospital and house surgeon at the West London Hospital from 1863 to 1864. In the next year he commenced general practice in Hammersmith, where he remained until 1899, during which time he built up a large practice, holding at one time and another the appointments of Poor-law medical officer, public vaccinator, and surgeon to Oddfellows and other friendly societies. During the epidemic of cholera in 1866 he was appointed a special medical officer by the vestry, as also in two epidemics of small-pox.

Dr. Alderson took the liveliest interest in every matter that affected the medical profession; he was for over 30 years a member of the board of management of the West London Hospital and was an active supporter of that institution. He was one of the founders of the West London Medico-Chirurgical Society and was fifth president in 1886–87, reading for his presidential address an interesting and well considered paper on "The Wants of the General Practitioner of the Present Day"; he remained a vice-president of the society until his death. He was president of the Incorporated Medical Practitioners Association in 1893 and was one of the most active members of the profession in endeavouring to obtain increased Direct Representation on the General Medical Council. In 1891, in conjunction with Mr. George Brown, he sought election as a Direct Representative on the General Medical Council, polling 4816 votes, and although unsuccessful was again a candidate in 1896, standing as an "Independent" with non-success as an almost foregone conclusion. At this election the apathy of the profession in the matter of Direct Representation on the General Medical Council was remarkable, only 11,990 voting papers being returned, 22,577 having been issued. He assisted in the formation of the London and Counties Medical Protection Society and he was a member of its council and of the executive committee of the Royal British Nursing Association, the interests of which he worked hard to promote. He gave evidence before the committee of the House of Lords on "Hospitalism" in 1891. In 1899 Dr. Alderson retired from practice and went to live at Bournemouth. Here, while still retaining his great interest in things medical, he found time to take an active part in local affairs as a guardian territories hitherto under the desolation of disease. Yet to be ministers of a newborn profession is not all loss. When Athene sprang full-grown from the head and heart of Zeus, were not the Olympians at first a little disdainful and aloof, and the divine maid a little wondering and shy? And probably the ægis was not quite ready; these artificers are always behindhand. Is not Medicine, born full-grown from the womb of our own time, if a little wistful at first, spared the hamper of a long past? Her gospel is not hidden behind an ancient and creaking machinery, nor are her eyes bent away from the future by a huge inheritance of undigested facts and opinions. The engineer, it is true, is a new demi-god, but he deals with far more elementary things; with means, not with ends. Joyfully we are putting on a hundred legs for one in the hope of escaping from ourselves, yet so far it seems very much in vain.

MINISTRY OF HEALTH.

What is now needed in England is no halt by our leaders, but the establishment of a General Staff of Medicine, to rebuke the purblind and inveterate habit in our countrymen of devoting their magnificent energy and their treasure to mopping up effects, in disregard of causes; to teach them better than to hustle each other with fussy, belated hurryings to and fro after evils have surged to a head, as, for instance, in the calamity of plague in India and in the typhoid disaster in South Africa; calamities no longer mysterious, noonday pestilences concerning which the modern physician had ample foreknowledge. Yet with all this knowledge, and infinitely more parcelled out in the several closets of the older ministries, or submitted to the patronage of selfish and awkward local authorities, generally coarse and inconsistent in their methods, and sometimes corrupt, medicine, as a function of the State, is still working as it were with her left hand. Her scattered official members have no unity; working piecemeal everywhere she has no coördination, no integrated self-consciousness. With no fixed apparatus for concerted action, energy is wasted in overlap, in jostling, in divided purposes, and in anomalies. Although her influence has penetrated into almost every function of society and directly and indirectly she is spending a great revenue, yet through the counsels of the nation she passes veiled and irresponsible. The new ideas which are stirring society are largely medical, yet society does not know where, in the back staircases or garrets of the Local Government Board, of the Home Office, of the Education Office, of the Board of Trade, of the Post Office, of the Registrar-General's department, of the Lunacy Commission, and so forth, each bee buzzing in its own little cage, medicine is to be found; nor how this new solvent and all-pervading influence are to be brought to the back of revenue or to the bar of public opinion and responsibility.

Our charge.—Let us consider, but for a moment and in outline, the charge of medicine in normal national functions. Abroad public medicine, which short-sighted people seem even still to see only through the taint and clatter of "hygienic" trade advertisements, public medicine, to which private practice must begin to play a subordinate and tributary part, has stretched out its arm beyond the several nations, is transforming the quarantine of man, animals, and plants, and creating a vast and masterful international service. At home to public medicine is intrusted, in the first quarter of life, the reckoning of births; the protection of infant life and growth; the valuing of each generation by comparison with the past and with normal standards of physiological institution. The new measure of medical school inspection, a far-reaching measure the full purport of which as yet the country has but little notion, the physical and mental conditions of education, the "half-timer," and night-school problems; in later life the conditions of labour, the dynamics of food and the minimum wage, the how and the why of premature old age, the effects of degrading and stupefying labour, and the time incidence of old-age pensions; factory inspection, with estimates of the effects of particular trades, such as chemical works, mining of all kinds, metal grinding, and so forth, with their consequences and pecuniary compensations; and more broadly, the large problems of "eugenics," of housing, of home life, of ventilation, of water-supplies, sewage and rivers pollution, food markets, and the adulteration in England so rampant, and, furthermore, those amenities of life, especially in cities, which by their play upon the receptive organs of the mind, make for the temperance and harmony which are essential to health and function. Such, in the sphere of the normal, are a few glimpses of the functions of modern medicine.

If now we turn from the normal to the abnormal, we may as rapidly note the survey not only of the tides of epidemic diseases in the largest sense of man, animals, and plants, but also of the more chronic but no less mischievous diseases which in large degree depend upon defect or vitiation of the conditions of social life; the proclivity to reversion and degeneration which is the shadow of evolution; the prevention and treatment of feeble-mindedness and insanity, which after mountainous waste of means is hardly begun; the great problems of hospitals and sick asylums; the urgent problem of a provision for medical and surgical treatment for large classes above the very poor, upon whom long and costly illness falls with a crushing weight and by whom in any case the consummate therapeutical apparatus of hospital charity are unattainable; the working of the Poor-law; the campaign against drunkenness, fornication, and other venomous social vices; and thence to criminology and punishment, to toxicological and expert medical testimony, to the anomalies of coroner's courts which in the crudity of their procedure would seem to exist rather for the destruction than for the corroboration of evidence; and finally, to the antiquated and distrusted dogmas of the judges of the higher courts on responsibility before the law.

Now this is the baldest of sketches, yet does it not indicate that modern medicine is embracing not indeed the final purposes and issues but the springs and conditions of national and universal life and efficiency; yet while the central administration remains as acephalous as the peripheral parts are multifarious and incoördinate, can we wonder that ignorance, confusion, and vacillation still prevail? The medical officer of health is at the mercy of the caprices of any interested clique; his sphere is undefined, he has neither protection nor freedom. In the service there is no order of promotion, no assurance of pension. Thwarted in detail, and in no public coöperation with a consolidated service, he is apt to lose standards, to lose efficiency, and to lose heart. Without an organised State department, public medicine lacks the corporate sense of a great official body like the law, and the stability of the coherent social groups which are favoured by natural selection. Moreover, being human, its partial conceptions, cross purposes, and pedantries are thus unmodified; and its naturally strong positions are not fortified against lay criticism; so that the public does not feel at home with medical ideas and practices. Working behind the scenes it loses the discipline and the chastisement, as well as the honour of public responsibility; while in the words of the President of the Royal College of Physicians of London,[2] "the State thrusts upon us responsibilities which are not ours." Unrepresented by a Minister of its own in Parliament, by alien Ministers it is alternately used and betrayed; and in silence must submit to hear its motives misinterpreted, its methods mishandled, and its unrequited labours continually imposed upon.

To one more factor of medical organisation I can but allude, although it lies at the root—I allude to the making of knowledge, knowledge of all national stores the most precious, in spite of the overlords of society who, as I have said, cling still to a belief in the efficacy of ignorance and delay. Grave towards us as are the faults of the Local Government Board, we must gladly admit that in this department some research is fostered. It is clear that there must be administrative laboratories and that without the atmosphere of disinterested research the best laboratories must flag; still it is open to inquiry how far the State shall make knowledge for itself and how far it shall derive it from universities and other scientific bodies. But when, for science or for art, money is wanted we learn that we are the poorest nation in the civilised world.

What are we to propose, then, in reform of the services of public medicine? It is understood that in high quarters the desire is to begin with the chaotic and inefficient periphery, in the hope that, secondarily, evolution may reach, recreate, and coördinate the subcentres and the main centre. It is urged also that each department must have its own medical bureau for its own continuous guidance and instruction. Again, there is the conventional dread of medicine as

---

[2] THE LANCET, Oct. 5th, 1907, p. 945.

Executive Officer, Education Offices, Victoria Embankment, London, W.C. The forms of application must be returned to the same address not later than Saturday, Oct. 17th next.

UNIVERSITY COLLEGE HOSPITAL.—Mrs. Berkeley Hill has presented to University College Hospital, in memory of her late husband, a very interesting group of the portraits of his colleagues in the year 1891.

NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC, QUEEN-SQUARE, BLOOMSBURY, W.C.—The first lecture of the winter term will be given by Dr. James S. Collier on Tuesday, Oct. 6th, at 3.30 P.M., on Local Lesions of the Spinal Cord—Anatomy.

THE medical exhibition under the management and supervision of the *British and Colonial Druggist* will take place at the Royal Horticultural Hall, Vincent-square, London, S.W., on Monday next, Oct. 5th, and the four following days. The exhibition will certainly be of interest to members of the medical profession.

THE WINSLEY SANATORIUM FOR CONSUMPTIVE PATIENTS.—The quarterly meeting of the board of governors of the Winsley Sanatorium was held at Bristol on Sept. 16th under the presidency of Dr. R. Shingleton Smith. It was decided to admit patients from outside the counties of Gloucestershire, Wilts, and Somerset on payment of 2 guineas weekly, so long as beds were available without depriving patients within the three counties. The medical officer of the institution having resigned, it was decided to advertise the appointment, the salary to be £200 per annum, rising by £20 a year to £300. The financial position of the sanatorium was carefully considered and it was stated that an additional income of £600 a year was required.

KING'S COLLEGE (UNIVERSITY OF LONDON): PRELIMINARY AND INTERMEDIATE MEDICAL STUDIES.—During the long vacation extensive additions have been made to the anatomical department and the area of the dissecting room has been largely increased. Complete equipment is now provided for research work in anatomy and embryology. The College provides the fullest facilities for students in all subjects connected with preliminary and intermediate work, both for those wishing to pursue the whole course and for occasional and research students. A student desirous of obtaining a medical degree in London can begin his career by attending courses as a university student at King's College and after passing his intermediate examination can select any of the London Hospitals in which to complete his studies.

ROYAL SANITARY INSTITUTE.—A provincial sessional meeting of this institute will be held at the City Council Chambers, Guildhall, York, on Saturday, Oct. 17th, at 11 A.M., when a discussion will take place on "The Architecture and Sanitation of Elementary School Buildings." The discussion will be opened by Mr. J. Osborne Smith, F.R.I.B.A. It is hoped that the following will take part in the discussion: Dr. R. H. Crowley, medical superintendent, Bradford education authority; Dr. J. Mitchell Wilson, medical officer of health, East Riding of Yorkshire county council; and Mr. H. R. Morrell, head master, Scarcroft School, York. A general discussion is invited. The chair will be taken at 11 A.M. by Mr. H. D. Searles-Wood, F.R.I.B.A., chairman of the council of the institute.

DONATIONS AND BEQUESTS.—Miss C. F. Foster of Norwich has among other bequests left the following: £200 each to the Deaf and Dumb Asylum, Old Kent-road, London, the Eastern Counties Asylum for Idiots, Colchester, the Hospital and School for Indigent Blind, Norwich, and the Norfolk and Norwich Eye Infirmary, £500 to the Jenny Lind Infirmary for Sick Children, and £1000 to the Norfolk and Norwich Hospital.—The late Colonel James Reid of Greenock has bequeathed £1000 to the Greenock Infirmary and £500 each to the Eye Infirmary and the Greenock Medical Aid and Sick Nursing Society.—Under the will of Mr. Thomas Beeley of Manchester the testator bequeathed £500 to the Ashton-under-Lyne Infirmary for its Endowment Fund.—The late Mr. Francis Verrall of Lewes and Crowborough has bequeathed £500 to the Lewes Dispensary and Infirmary and Victoria Hospital, Lewes.—Miss M. B. Johnston of Widcombe, Somerset, has bequeathed £1000 each to the Cancer Hospital, London, and the Royal Free Hospital, London.

THE DEVON COUNTY ASYLUM, EXMINSTER.—At a meeting of the Devon county council held on Sept. 24th it was decided to erect six additional cottages at Exminster Asylum at an estimated cost of £1500; and it was determined to vote £1200 towards the cost of the new sewage disposal works at Exminster, subject to the approval of the Local Government Board.

LONDON HOSPITAL MEDICAL COLLEGE.—The following entrance scholarships have been awarded for the session commencing Oct. 1st, 1908: Price scholarship in science, value £120, D. E. Morley. Science scholarships: value £60, J. R. K. Thomson; value £35, A. R. Elliott. Epsom scholarship: value £126, K. Biggs. "Price" scholarship in anatomy and physiology, open to students of Oxford and Cambridge Universities, value £60, H. Scott Wilson, B.A. (Queen's College, Oxford).

QUEEN VICTORIA JUBILEE CONVALESCENT HOME, DURDHAM DOWNS, BRISTOL.—A bronze tablet has recently been placed in the entrance lobby of this institution. It bears the following inscription:—

> In honour of Her Gracious Majesty Queen Victoria; in Memory of a Beloved Wife; and in sympathy with the suffering, this house was given by Sir E. P. Wills, for a Convalescent Home, on the occasion of the 60th Anniversary of Her Majesty's Accession, June 20th, 1897, and the home was opened by Her Majesty on November 15th, 1899. A.D. 1908.

This convalescent home is doing excellent work, and since its opening 12,400 patients have been admitted.

GUY'S HOSPITAL MEDICAL SCHOOL.—The following entrance scholarships and certificates have been awarded: Senior science scholarship for University students (£50), Nathan Mutch, B.A., Emmanuel College, Cambridge; certificate, H. W. Barber, B.A., Clare College, Cambridge. Junior science scholarships: £150, J. F. G. Richards, Preliminary Scientific (M.B.) Class, Guy's Hospital; £60, W. L. Webb, Preliminary Scientific (M.B.) Class, Guy's Hospital; certificate, G. S. Miller, Preliminary Scientific (M.B.) Class, Guy's Hospital. Entrance scholarships in arts: £100, A. J. E. Smith, Rugby School; £50, H. W. Evans, Modern School, Bedford.

NEW HOSPITAL FOR LYDNEY (GLOUCESTERSHIRE) AND DISTRICT.—On Sept. 24th Sir Charles Dilke, M.P., in the presence of a large gathering formally opened the new hospital for Lydney and district. The building comprises two wards of four beds each, operation theatre, dispensary, &c. The site was given by Mr. C. Bathurst and Mr. R. Thomas has defrayed the whole cost of building the hospital. Mr. Bathurst suggested as a means of providing an "endowment fund" that if the public would subscribe £800 for this purpose by the time the hospital was completed he would make the sum up to £1000. The public has responded to the appeal and there is no doubt that the required amount will be raised.

Appointments.

Successful applicants for Vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column, are invited to forward to THE LANCET *Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week, such information for gratuitous publication.*

ADKINS, GEORGE, L.R.C.P. Lond., M.R.C.S., L.S.A., D.P.H. Camb., has been appointed Medical Officer of Health for the County of Devon.

BRUCE, ERNEST, L.R.C.P. & S. Edin., L.F.P.S. Glasg., has been appointed a Medical Inspector of Schools for Swansea.

COOPER, J. BURDON, M.D., B.S. Durh., F.R.C.S. Edin., has been appointed Honorary Ophthalmic Surgeon to the Bath Eye Infirmary.

DAVIES, JOHN LEWIS, M.B., Ch.M. Edin., has been appointed a Medical Inspector of Schools for Swansea.

DOBIE, E. C., M.B., M.S. Edin., has been appointed Senior Honorary Surgeon to the Chester Infirmary.

EDWARDS, DAVID RICHARD, L.R.C.P. & S. Edin., L.F.P.S. Glasg., has been appointed a Medical Inspector of Schools for Swansea.

EVANS, JOHN, L.R.C.P. Edin., L.F.P.S. Glasg., has been appointed a Medical Inspector of Schools for Swansea.

FROST, JOHN KINGDON, M.D. Durh., M.R.C.S., L.S.A., D.P.H. Camb., has been appointed District Medical Officer and Medical Officer to the Workhouse by the Dorchester Board of Guardians.

we not by levelling down university standards and forcing up technical machinery attain a certain efficacious mean? Now it is a litt'e irksome to me to contest this proposition, for in former addresses, before audiences too much wedded to abstract academic methods and prone to edge away from concrete processes, processes which, no laboratory ingenuity can imitate or even conceive, I have urged that, Antaeus-like, knowledge must continually be recharged by earth contacts. Universities are no longer to be the cloisters of subtle and fastidious persons, observing the wind, and all a little afraid of each other. Albeit this return to the realities of life is not to be for the accommodation of mean positions but for the achievement of still wider knowledge. The mean position, as social history tells us and as biologists are illustrating, is a position not of advance, not of growth, but of retrogression. As Professor E. H. Starling said, we cannot get a quart into a pint pot; but by these measures I would figure, not the potential capacity of the student, but the stricter capacities of our respective methods. Not by any shift can a pint method be dilated into a quart method; the pot may be filled to the pint peg only, if no more can be afforded, but if it is to hold a quart it must be designed on the lines of the quart from the commencement.

There is no escape then from the unpalatable truth that if a liberal education, the education of a university, the making of the man, is to preside over the making of the particular professional man he must pay the price. Be the technical call for time such as it may—five years, say, or six—if the original capacity of the individual is to be brought out, if his personality is to be developed before, and also hand in hand with, his adaptation as a special instrument, some enlargement of time and opportunity has to be given and paid for. Narrow circumstances may deny it to him, they deny us many excellent things; but in this case the average man will never fully find himself, he will be designed as a receptacle and a retailer, and on the lines not of a progressive but of a stationary practitioner.

CONCERT OF METHODS.

Happily, however, with some mutual adjustments, the creative and the instrumental methods may be combined and the double price in time and money reduced. If the function of a university is to be the maker of the man as a whole, it cannot properly be made responsible for his technical efficiency as a practising lawyer, a practising parson, a practising physician; as a soldier or an engineer in the field. Nevertheless, theology, law, medicine, military history, engineering, and the like are taught in universities, and herein it is that university ideas and the hard-pressed student and his guardian may approach each other. For to develop the individual faculties, and to create the man, almost any subjects can be used if they are used thus as universals; not as particular equipments, not as furniture, but as disinterested means of unfolding the secret powers of the mind. Yet it is at this very crux that Professor Starling would desert us. If I read him aright he would, while in the university, curtail these convenient studies from educational to instrumental purposes, thus neutralising the very principles on which an accommodation between liberal and technical ideals is practicable. For instance of anatomy, the university, on his suggestion, is no longer to teach anatomy as a means of culture—a disinterested anatomy, to awaken and develop the general faculty of exact observation, and to imbue the mind with broad morphological and genetic principles, but, instead of this disinterested study, sections useful to the future craftsman are to be extracted; neglecting the development of faculty we are to confine ourselves to the inculcation of immediately useful parcels. This is indeed to shape the instrument before we have forged the steel. I have never forgotten the day when Humphry put a bone into my hand and revealed to me as an undeveloped youth what scientific observation meant; it meant not just points for the surgeon, for surgery then formed little or no part of the Cambridge curriculum, but a training of faculty, whether for the physician, the naturalist, the physicist, the palæographer; in a word, for universal education. Thus one realises how carelessly the untrained eye skips its reading; had I been told to note only what I might happen for some practical purpose to want, and to skip the rest, the eye would have fluttered unchastised over many a tiny point, which afterwards, when the mind had been raised to the conception of principles, would have revealed itself as an "expression point," significant of cycles or deviations of growth which otherwise had left no trace. "To look with the eye confounds the wisdom of ages." Moreover, in the unforeseen future, as, for instance, in the field of modern neurology, it is the anatomical habit of mind, apart from the memory of details, which in great part gives his lead to the successful observer in new spheres of observation. Such in anatomy is a part of the contrast between universal and technical methods, but such also are the potentialities which enable us to use almost any department of knowledge for an education of universal quality.

Secondly, if time be gained thus, we shall find other gains also at a later stage. The maturer and more various the qualities the mind brings to bear, the more quickly and truly will it judge of what is to come before it later. The teacher's ideas have not to dwindle into the dimensions of a rudimentary disciple. The technical instruction, which it is his turn to give, falls upon a mind already familiar with standards, with principles, with relative values; a mind accustomed to observation, comparison, and foresight. Moreover, among themselves, such educated students do not, as those who are only of the workshop, operate upon each other at low levels, but they stimulate each other with spontaneous inquiry and critical judgment. In this search after truth their minds have found themselves, and this search is the path of life: they have that awakened sense of our ignorance which forbids us any satisfaction in phrases and conventions; which tells us that none of our axioms is true, though truer than an indolent or gregarious assent, and guards us against the domination of the many positive persons who do not know but only assert; such as the historian of whom Acton said that "a little study of the subject would probably diminish the severity of his judgment and add materially to its weight." For students thus educated technical attainment is greatly accelerated.

Thirdly, we may gain time for an enlarged curriculum by requiring more of the secondary schools, and by encouraging our students to come up a little younger. At Cambridge we have decided to offer the First M.B. examination to candidates on entrance, so that with us they may proceed at once to more advanced subjects. In the Sheffield discussion Dr. Dawson Turner was jealous lest thus the literary side should be starved; I find but little of a literary side to starve, but in any case may we not have an equal jealousy of the literary schoolboy starved of science! The elements of science required for our First M.B. are of the kind which should enter into the formation of every educated man.

Much, then, may be done, by preparation, by consolidation, and by adaptation, to fit together university and technical education; but no consolidation, no contrivance, can make them identical or equivalent. Whatsoever may be the time prescribed by the Medical Council for qualification, the student who desires to build up his faculties by a more universal training must add a year or two to the technical minimum, and this from the beginning of his course. It cannot be tacked on at the end of it.

Is it not, then, deeply to be regretted that a great Lancashire merchant, a man of energy and powerful in material progress, should use his influence to declare that "a university education retards a young man's progress in commercial life, by occupying years in the study of classical and other subjects when commercial training would be more valuable." Now he must be a very dull or a very complacent observer who supposes our modern industrial civilisation to be hitherto a great success; still what an abasement, surely an unmerited abasement, to suggest of commerce, for which ancient calling this and other universities are now giving new opportunities, that it is all trivial; that it is incapable of principles, of high standards, and has no uses for an education which stores the mind with liberal knowledge and opens it to new and various ideas. We have seen that a disinterested building up of mental faculty is not a matter of this study against that, whether of literature, of social and commercial economy, of physical science, of history, and so forth, but of the larger manner of its handling; that university training does not consist in decorative accomplishment, nor in disdain of common things, but in an openness and a flexibility of mind to new issues, in the spirit brought to the study of everything; for although in nature nothing is common, no

Notes, Short Comments, and Answers to Correspondents.

THE QUACK BLATANT.

r. C. E. Richmond, B.Sc. Vict., F.R.C.S. Eng., forwards us a particularly flagrant quack advertisement from the *Manchester Evening Chronicle*. It runs:—

> ACTED AS A DOCTOR.
>
> THE REASON FOR THESE PERSECUTIONS.
>
> Some years ago, a Conference of Doctors was held for the purpose of deciding upon some way of crushing me, when it was resolved to refuse all my death certificates (which I had given for over 20 years, and had been accepted), and to hold an inquest upon every death.
>
> NOW LET US SEE WHO ARE THE QUACKS.
>
> One of my present customers is a lady I cured of Cancer of the Breast. She has since had a child and suckled it from the same breast. Still living, and mother and child will bear testimony. I forgot to say she had previously been under the legally qualified doctors, who wanted to cut it out.
>
> 1. At the present time I have a customer coming with Cancer of the Tongue. Undergone two operations, and advised to do so a third time. Came to me, and is doing well with Febrifuge treatment.
>
> 2. Man came fortnight ago. Stricture, under doctors long time, had fourteen operations, and was finally told he would have to be operated upon all his life. Febrifuge brought the water away first bottle. Is now doing well.
>
> 3. Young woman with Whitlow of the Thumb. Been in hospital, doctors wanted to amputate; almost well after three weeks' treatment.
>
> THESE ARE A FEW FACTS—MORE IN TO-MORROW'S ISSUE.
>
> GEORGE JACKSON,
> Proprietor of Jackson's Febrifuge,
> 870, Rochdale Road, Manchester.

We do not know whether this person was ever on the Medical Register. If that were the case we rejoice that he is now off it. If he were not, the statement that his death certificates were accepted for 20 years is a piece of impudence which deserves the attention of the Manchester registrar, for he seeks clearly to imply that they were accepted by that official. Mr. Richmond in a covering letter expresses his indignation at the fact that qualified practitioners of medicine have no protection against the competition of such ignorant quacks. As we have pointed out over and over again, the great share of responsibility lies with the newspaper proprietors. The experience of other countries and other ages renders it almost impossible to hope that medical practice by unqualified persons can ever be adequately suppressed by law. But it is within reason to hope that some day Parliament may see fit to forbid the insertion of their monstrous claims in the columns of newspapers.

A POINT IN MEDICAL ETHICS.

To the Editor of The Lancet.

Sir,—Noticing a letter written by an M.R.C.S. and L.R.C.P. to you, I should rather like to call attention to an incident which came under my notice and which in some respect bore a resemblance to this particular case. A medical man called at my office and we conversed for about half an hour on the subject of the purchase of a certain practice. I was in a position to give him particularly full details of the practice as the vender was personally known to me and had called on several occasions respecting the proposed sale. The would-be purchaser, having obtained all details, visited the practice in question, and then decided, for some reason, not to buy it.

To my extreme surprise I afterwards heard that the very man who had obtained particulars of the practice had started on his own account within a very short distance of the would-be vendor's house, and subsequently the vendor writes a letter to me stating what has happened, and I, in reply, advised him that it would be absolutely impossible for him to sell fairly, anyhow for the present. It was particularly unfortunate for him, as his health was bad and necessitated him leaving the practice to recuperate for weeks at a time, which fact I had carefully pointed out to the man who received particulars of the practice from me. (The intending vendor having since died, in a sense confirms the bad state of health he was in previously.) The action of the doctor who had the particulars from me of course rendered it impossible for the would-be vendor of the practice to transfer it, as any intending purchaser going down to the place would at once notice that there was a practitioner close by, and his first question would probably be, "How long has he been there?" or the vendor, if he were not asked such a question, would, if he were an honest man, inform the intending purchaser that his neighbour had only recently started. Agreed that it is somewhat hard for a man to be debarred from practising in a town because he has particulars of a practice there, yet at the same time it seems absolutely impossible to me for a man to conscientiously "put up his plate" in the said town should he have received fully discussed particulars of a practice for sale, and particularly in the instance of a man who was in reality selling his practice because his health would not allow him to continue his practice with any comfort to himself or carry out his duty to his patients. Thinking that you might like to hear another view on the same unquestionably important subject and apologising for trespassing on your valuable space,

I am, Sir, yours faithfully,
A Medical Agent.

EARLY ENGLISH MEDICAL BOOKS.

To the Editor of The Lancet.

Sir,—Concerning early medical books in English I did not suggest that the "Governal of Health" was the earliest English "work." I said "book," which, I think, means (whatever may be the dictionary definition) a printed work. I should not term a manuscript a book, for although it may be divided in sections called "books," in every catalogue I receive a distinction is made between manuscripts and books. With regard to the earliest manuscripts being of the fourteenth and fifteenth centuries, surely this is a mistake. To quote only one instance: there is a collection in three volumes of early Saxon medical works, entitled "Saxon Leechdoms," which are certainly much earlier.

I am, Sir, yours faithfully,
Oscar Jennings.

THE "LITTLE LEARNING."

The following extract is from the leading columns of a provincial newspaper, for unearthing which we are indebted to the *Guy's Hospital Gazette*. The versatile writer was seeking to mould his readers' minds on the problems raised by Mr. Francis Darwin at the recent meeting of the British Association for the Advancement of Science. He asks:

> "What is ontogeny? It is, we presume, a process of development, either in plants, in the lower animals, or in man. The epigenetic point of view, we may similarly surmise, is that of those who hold that the germ of an organism does not pre-exist in the parent, but is brought into existence by the parents' powers of procreation.
>
> "Here, again, we pause to inquire who and what are the somatists? They are those who believe in the inheritance of acquired characters. The designation, which is new, is rather far-fetched, but has a certain applicability, soma being the juice of a plant offered in libation to a Hindu god to strengthen him in his fight with the demons. It is identified—and here its applicability comes in—with the invigorating and immortalising principle in nature."

It is true that the modern journalist is expected to have a range of information universally wide, if of no appreciable depth, but the letters to the editor which the above contribution to the thought of the age must surely have called forth may perhaps give its writer pause before he again rests so pretty an interpretation upon the single authority of an encyclopædic dictionary.

THE MYSTERY OF THE LAW.

To the Editor of The Lancet.

Sir,—Two years ago the wife of a tradesman called me in to her husband who was suffering from pernicious anæmia. After four months he died and the widow went away without notice. After some time I found her living in a private house with an aspect of great comfort. She expressed regret and paid about a quarter of my account. To further applications she was deaf. Acting on the advice so liberally bestowed upon us in the columns of the daily press I took out a summons. As I know that solicitors consider debt collecting beneath their dignity I did this personally. Her solicitors then wrote offering half of the amount of my claim in settlement. Secure in the justice of my case I declined this and went into court. To my utter astonishment the county court judge decided that I had no claim, but advised the widow to make me "a small offer." I make no complaint of the judge's ruling. I suppose that he gave me good law, but where is the equity or the sense? If it had been a curable case the man might perhaps have paid me. As it was a hopeless one, demanding close attention and one consultation, I am entitled to nothing.

I long for the happy days of the nineteenth century, when people paid their doctors.

I am, Sir, yours faithfully,
Retrorsum.

A THEORY CONCERNING THE RELATION OF BACTERIA TO DISEASE.

To the Editor of The Lancet.

Sir,—Diversity of opinion inevitably tends to the advancement of science, and a new theory, even if it be wrong, affords fresh material for reflection and often throws new light on some obscure doctrine. The influence of bacteria in the causation of disease has of late years been generally recognised and in many instances the presence of bacteria has been considered the sole proof of the existence of a specified disease. The diagnosis of disease would indeed be simplified if for every ailment a definite bacillus could readily be detected, but practical experience has amply demonstrated that this simple method of arriving at a correct conclusion has not as yet been perfected. But even granting specific bacteria existed in every disease and were capable of being recognised, very slight advantage would accrue, experience, may ripen into a kind of intellectual power. And if we ask how this may be the answer is not very remote. The zone of our intensest life is not in the individual alone, nor again in the universe alone, but in the weaving edge between them. The tissue, as on the personal side it is wrought, we have to guard from decay; but the weavers' vision and hand, by an intuitive gift of insight and touch beyond common reckoning, are swiftly conceiving the pattern and designing the web. As Professor James says, "ideal impulses possess us in a most unaccountable way, and work gets done." Thus after his fashion every man of action, even the man of science, is an artist; it is by imaginative vision that he gives birth to the new ideas, which he then compares and approves by intellectual judgment. We know in part and we prophesy in part. This zone or phantom verge of intensest vital activity, this halo of creative life between the individual and his *milieu*, in ethics is faith and hope; in work is purpose and enthusiasm; in art is creation; in science is that spirit of research which is confined to no laboratory but sees in every patient a new problem for interpretation and succour.

Your beliefs then are integral constituents of your lives, and are your driving power. For with duty or values, or even with ends, the equal eye of science has no concern. And if any one of you thinks he has no belief he lies in grievous error. Consciously or not, each one of you is harbouring his own ideal of life, good or bad, and is living by it; if the moth gets into it your character will decay with it, and so will your influence on others. Mark then, day by day, the order of your springs of action, that your hearts may be lifted up, and the continuity between will and action quickened and knit together. We have seen that to progress we must be living above the mean position; and as modern philosophy postulates that our several worlds are not outside us but within us, and are what we are, we realise that the world is what we make it; and that our maturer responsibilities cannot be ordered by any external authority. In the words of an accomplished author, Miss Mary Cholmondeley (I forget in which of her interesting stories): "How many rush hither and thither, and wear down the patience of earnest counsellors, and all the best years of their own lives in fretting and scratching among ruins for the law by which they may live! They look for it in books, in the minds of friends, in the face of Nature who betrays in her eyes the knowledge of the secret but utters it not. And last of all a remnant of the many look into their own hearts, where the great law of life has been hidden from the beginning."

For the pattern and governance of your daily lives I am thankful to say that in our own profession you will find a true and helpful example. Conversant during a long life with the homes of medical men I have felt rebuked again and again by their devotion to duty, their peerless generosity, their self-respect, and simplicity of manners. Faultless we are not, as more than once I have dared to say. Besides the temptations common to all men we have temptations peculiar to ourselves. Our patients, loyal and grateful as most of them are, disappoint us at times, and these disappointments may be very galling. In these days of rather aimless unrest they are too apt to forget the importance of continuity of observation and treatment. The consultant gives counsel indeed, but upon the family physician, who knows the whole story and sees the daily strains, depend the patience, the vigilance, and the discrimination needed to compass the cure. Yet too often, and perhaps by a tea-table cabal at a critical time, the patient is whisked off to some "specialist" who has an Installation, an Institution, a Home, or a Spa, which has to be kept agoing —*recte si possit!* And to the patient life is very dear; his judgment is enfeebled by illness and care; he clutches at any fair promise of aid; and the physician must remember that he also is human and that when ill himself he is apt to run hither and thither quite as inconstantly.

And are we not more to blame when our imaginations, kindly for others, stop a little short of our own brethren; when we are not quick to put ourselves in the place of him whom we are unhappily wont to designate not by the word of brother, but of "opponent"? Now words sink into our minds like stones. The relations of medical men in small societies are delicate, and with the best intentions misunderstandings are apt to arise, and to be aggravated by busybodies. If, indeed, our medical neighbour be not very fraternal, not always perhaps very high-minded, we must remember that herein lies one of our special temptations; and, if only for our own happiness and peace of mind, we must be a little blind to his faults and endeavour by our conduct to bring out not the worse but the better part of him. There is more awkwardness in these matters than malevolence, and there is nothing high-minded in being quick to take offence.

You may be tempted to say that it is all very well for me at my time of life thus to pose as your philosopher, and to set before you intellectual and moral ideals which you cannot hope in this rough and tumble world to attain. But to hitch our wagons to a star is not to reckon on camping in it at nightfall. An ancient sage has told us: "In magnis et voluisse sat'est"; a modern poet puts it: "It is not what I was but what I aspired to be which comforts me"; or, as we say in our strong northern vernacular: "He did his best, and he couldn't do nowt else."

Abstracts

OF

INTRODUCTORY ADDRESSES, ETC.

DELIVERED AT THE

MEDICAL SCHOOLS

AT THE

Opening of the Session 1908-09.

ST. GEORGE'S HOSPITAL.

INTRODUCTORY ADDRESS BY CHARLES SLATER, M.A., M.B. CANTAB., SUPERINTENDENT OF THE CLINICAL LABORATORIES, AND LECTURER ON BACTERIOLOGY.

Dr. Slater, who took for his subject "The Laboratory in Medical Education and Practice," first acknowledged the tribute which had been paid to the laboratory in his selection as opening lecturer, and welcomed the newly joined students "to a school with great traditions—traditions centring round the names of Hunter, Young, and Jenner—carried down through Brodie, Hewitt, Holmes, and our own teachers." He then proceeded to outline the great advance which had been made in the last 30 years in laboratory methods in connexion with clinical and preventive medicine, especially in the development of the science of bacteriolgy. He continued: "During this period the education of the public in a knowledge of these advances and in an appreciation of the advantages to be gained from them has progressed. Many of the discoveries and their applications have yielded picturesque if inaccurate copy to the lay press and have been eagerly seized upon. Mr. Balfour in a recent visit to this hospital remarked on the comparative simplicity of the task of the defenders of vivisection before the Royal Commission then sitting to consider this question compared to the similar task in the time of the earlier Commission which he recalled; a simplicity due to the array of striking illustrations of the advantages gained by these methods, and capable of appreciation by the layman, which could be adduced from the discoveries in connexion with antitoxin and other remedies and methods of treatment. The real education of the public in science is to be welcomed by the medical profession as it emancipates them from what Dr. W. Ewart has called the thraldom of the phial—the dominion of the quack—and makes them ready to appreciate, not by lip service merely, the connexion between cause and effect. At the same time it makes them more critical of methods and explanations—and as to how much do we still lack explanation—and will undoubtedly drive upwards the standard of general and professional education required of the members of our profession. During this period, then, the scientific basis of medicine has grown with phenomenal rapidity and this tree of knowledge has pushed out from its stem of physiology and anatomy such numerous and wide-spreading branches in experimental pathology that it has tended to overshadow the clinical side of medicine and has affected the medical schools, the medical education of the student both in its earlier, later, and post-graduate stages, and

tes, Short Comments, and Answers to Correspondents.

THE QUACK BLATANT.

C. E. Richmond, B.Sc. Vict., F.R.C.S. Eng., forwards us a par- ularly flagrant quack advertisement from the *Manchester Evening* *ronicle*. It runs:—

ACTED AS A DOCTOR.

THE REASON FOR THESE PERSECUTIONS.

Some years ago, a Conference of Doctors was held for the purpose of deciding upon some way of crushing me, when it was resolved to refuse all my death certificates (which I had given for over 20 years, and had been accepted), and to hold an inquest upon every death.

NOW LET US SEE WHO ARE THE QUACKS.

One of my present customers is a lady I cured of Cancer of the Breast. She has since had a child and suckled it from the same breast. Still living, and mother and child will bear testimony. I forgot to say she had previously been under the legally qualified doctors, who wanted to cut it out.

1. At the present time I have a customer coming with Cancer of the Tongue. Undergone two operations, and advised to do so a third time. Came to me, and is doing well with Febrifuge treatment.

2. Man came fortnight ago. Stricture, under doctors long time, had fourteen operations, and was finally told he would have to be operated upon all his life. Febrifuge brought the water away first bottle. Is now doing well.

3. Young woman with Whitlow of the Thumb. Been in hospital, doctors wanted to amputate, almost well after three weeks' treatment.

THESE ARE A FEW FACTS—MORE IN TO-MORROW'S ISSUE.

GEORGE JACKSON,

Proprietor of Jackson's Febrifuge,

870, Rochdale Road, Manchester.

We do not know whether this person was ever on the Medical Register. If that were the case we rejoice that he is now off it. If he were not, the statement that his death certificates were accepted for 20 years is a piece of impudence which deserves the attention of the Manchester registrar, for he seeks clearly to imply that they were accepted by that official. Mr. Richmond in a covering letter expresses his indignation at the fact that qualified practitioners of medicine have no protection against the competition of such ignorant quacks. As we have pointed out over and over again, the great share of responsibility lies with the newspaper proprietors. The experience of other countries and other ages renders it almost impossible to hope that medical practice by unqualified persons can ever be adequately suppressed by law. But it is within reason to hope that some day Parliament may see fit to forbid the insertion of their monstrous claims in the columns of newspapers.

A POINT IN MEDICAL ETHICS.

To the Editor of The Lancet.

Sir,—Noticing a letter written by an M.R.C.S. and L.R.C.P. to you, I should rather like to call attention to an incident which came under my notice and which in some respect bore a resemblance to this particular case. A medical man called at my office and we conversed for about half an hour on the subject of the purchase of a certain practice. I was in a position to give him particularly full details of the practice as the vendor was personally known to me and had called on several occasions respecting the proposed sale. The would-be purchaser, having obtained all details, visited the practice in question, and then decided, for some reason, not to buy it.

To my extreme surprise I afterwards heard that the very man who had obtained particulars of the practice had started on his own account within a very short distance of the would-be vendor's house, and subsequently the vendor writes a letter to me stating what has happened, and I, in reply, advised him that it would be absolutely impossible for him to sell fairly, anyhow for the present. It was particularly unfortunate for him, as his health was bad and necessitated him leaving the practice to recuperate for weeks at a time, which fact I had carefully pointed out to the man who received particulars of the practice from me. (The intending vendor having since died, in a sense confirms the bad state of health he was in previously.) The action of the doctor who had the particulars from me of course rendered it impossible for the would-be vendor of the practice to transfer it, as any intending purchaser going down to the place would at once notice that there was a practitioner close by, and his first question would probably be, "How long has he been there?" or [illegible] asked such a question, would, if he were an intending purchaser that his neighbour had greed that it is somewhat hard for a man to be debarred from practising in a town because he has particulars of a practice there, yet at the same time it seems absolutely impossible to me for a man to conscientiously "put up his plate" in the said town should he have received fully discussed particulars of a practice for sale, and particularly in the instance of a man who was in reality selling his practice because his health would not allow him to continue his practice with any comfort to himself or carry out his duty to his patients. Thinking that you might like to hear another view on the same unquestionably important subject and apologising for trespassing on your valuable space,

A THEORY CONCERNING THE RELATION OF BACTERIA TO DISEASE.

To the Editor of The Lancet.

Sir,—Diversity of opinion inevitably tends to the advancement of science, and a new theory, even if it be wrong, affords fresh material for reflection and often throws new light on some obscure doctrine. The influence of bacteria in the causation of disease has of late years been generally recognised and in many instances the presence of bacteria has been considered the sole proof of the existence of a specified disease. The diagnosis of disease would indeed be simplified if for every ailment a definite bacillus could readily be detected, but practical experience has amply demonstrated that this simple method of arriving at a correct conclusion has not as yet been perfected. But even granting specific bacteria existed in every disease and were capable of being recognised, very slight advantage would accrue, had considerable influence on the practitioner. This period has seen the public health services—the department of State medicine, the sanitary departments of the Services both military and colonial—become firmly established. There is no doubt that there will be further increase in this direction, a development of the medical officer at the expense of the general practitioner. As Dr. Ewart has so well expressed it, the profession is dividing itself into two uneven sections, that of practice and that of research. The latter works unpaid for the gain of the State and against that of the profession. There is a well-known warning as to the fate of a kingdom divided against itself. If the profession carefully watches the State, however, the effect will be to produce a *redistribution* rather than a *diminution* of the sources of emolument. The recent establishment of the system of school inspection of children has created a small army of officials and the introduction of a definite course of hygiene in the training of school board teachers must call for medical instructors. The present is not a bad time for the young medical man; the pinch comes in the later stages when promotion to the small number of higher posts becomes slow or ceases. Again to quote Dr. Ewart, the State has always gladly exploited the medical profession, and it behoves us to see that it does not develop its vicarious charity too greatly at our expense. The danger is not small. The public and the State have been accustomed to pay for cure and have not yet learned that it is much better to pay for prevention—they have yet to learn that to reduce the incidence of disease is worth a hundredfold more, expressed in hard cash, than the cure of the cases. We have to teach the public and public officials this. It has always been easier to get grants for the prevention of animal disease than for the prevention of disease in man because it has been possible to express the loss to the community in money terms. The State blinked at what Carlyle calls the cash nexus in the case of man on grounds of false sentimentality. But this same cash nexus is producing its effect on the insurance companies in regard to the prevention of tuberculosis and the support of sanatoriums. At present, however, the attitude of the official mind on learning of the reduction of a disease, as, for instance, the reduction of cases of enteric fever in the Indian army by 20 per cent. by our now highly trained army medical service, is to regard this as a chance to retrench the official or to diminish the special subsidies by which the improvement has been effected, regardless of the fact that the money expended, multiplied by the brains, has produced a hundredfold. It will be hard to root out this attitude from the official mind, even by the efforts of what I recently heard a distinguished surgeon speak of—without irony apparently—as our "powerful profession." It should be powerful, but I fancy the Cabinet Minister who was present and was engaged in this policy of exploitation smiled at this amiable delusion. However, thanks to the better organisation of the profession and to the better education of the official and the politician this abuse of the medical man will diminish steadily.

This growth of the official side of medicine has a secondary effect in prolonging the period of education and creating the compulsory attendance on what are practically courses of post-graduate teaching. The need for a diploma of public health is rapidly becoming a necessity for successful candidature for many appointments. The diploma may not actually be demanded, but a candidate who possesses it has such an advantage over his competitors that its absence is a barrier to employment. So far as this demand postpones the already long-deferred earning period of the medical man it is serious, but it must be recognised that medical education cannot stop at the qualification stage but must more and more involve post-graduate courses, and the work for the public health diploma is both valuable and interesting and not divorced from pure medicine. But ordinary medical practice has also become interpenetrated by the influence of the laboratory owing to the constant need for the latter's aid in diagnosis. The causes which led to the necessity for clinical laboratories in connexion with hospitals led to the provision of similar institutions in connexion with the sanitary services of towns and rural districts and to meet the requirements of the general practitioner. Some of these were official or semi-official and others were frankly commercial, founded, as the phrase is, to meet a much-felt want. Skilled as the modern qualified man may be in the use of scientific methods of diagnosis, the exigencies of practice, the want of time, the want of special apparatus, and a thousand other things make it advisable, if not absolutely necessary, for him to seek the aid of the laboratories of clinical research. The success of a method of investigation depends not only on the knowledge of the worker but on the technical skill gained by constant practice—a practice which must be very intermittent in the course of active professional work. But it is useless to insist on this point as the need is practically admitted, and the parcel of bottles, swabs, and blood tubes is as much a part of the physician's or surgeon's armamentaria as the stethoscope or the sterilised dressing. Every day adds a new method and a new direction in which the pathologist can aid the practitioner. The latest direction in which this aid may be furnished is in the diagnosis of syphilis in its early and late stages, and what would be of great importance should it prove possible, the determination when cure has been effected. It has been used to a considerable extent in Germany, but as yet but few observations have been reported in England. It is of interest from the scientific side as it does not depend upon the discovery of the spirochæta but on a method founded on a theoretical conception, the deviation of complement which a short time ago would have appeared wholly unconnected with any practical applications.

Now what is the kind of relationship which has existed or is to exist between the clinical laboratory and those who *employ its service? Is that relationship to be one of pure* commerce or a relationship of mutual help in solving a difficult problem? Are we to be merchants or scientific workers? You can make the relationship which you like, but the value of the aid you get will be very different. I would first put it as an appeal *ad misericordiam.* Have you ever realised what a soul-destroying industry it becomes to examine sputa, throat swabs, or urine without a word as to clinical details? Is it a wonder if this work is left in the hand of the assistant? It is only when the examination of the pathological product can be co-related with the clinical condition that we escape from commerce and get results of scientific importance. I know of one laboratory where it is an absolute rule that if the papers accompanying the request for an examination are not filled in with the clinical details asked for no report is sent; but it is not every laboratory the position of which is so secure or the finances of which are so sound that this position can be taken up. It is quite certain, however, that if we are to get the maximum benefit out of the laboratories, consultation between the clinician and the laboratory will have to be more resorted to. The financial difficulty, again, crops up, but I think it would soon prove that the pathologist's opinion based on a full knowledge of the problem was worth more than his report on an isolated specimen of morbid material. What is gained by trying to obtain an unbiassed report is far more than lost by the errors introduced by the want of information which would enable the pathologist to interpret his results and give a sound opinion. The old habit of setting pathological conundra to be guessed must be given up. At present, from one cause and another—all causes, however, which spring from lack of mutual consultation—a great many reports which are asked for and furnished are, and must be, useless, as the pathologist has never known what the clinician really wanted to learn, nor on the other hand has the latter discovered how the laboratory could best help him. I am far from undervaluing the difficulties which arise in this matter of mutual coöperation; a brief experience, and mine is now no longer brief, of the obstacles which arise as to a proper understanding between the laboratory and the clinician, even in a hospital where the conditions for such mutual help are most favourable, would soon dispel this delusion. There is always some natural hesitation in allowing the claims of a new class of specialist to enter into the crowded field of practice, and when these pretensions are pressed by one of the new class the argument may reasonably be regarded as not free from bias. The necessity of the consultant pathologist has, however, been recognised and his cause pleaded vigorously by Mr. A. W. Mayo Robson in a paper read before the Bristol Medical Society. At the recent meeting of the British Medical Association at Sheffield Dr. J. Kingston Fowler said: "The bacteriologist," and we need not confine it to him, "in some at least of the general hospitals is regarded as the servant of the physician who orders that certain investigations should be undertaken. This is not, I submit, the position to which he is entitled. In important cases in which his advice and

OPERATIONS.

METROPOLITAN HOSPITALS.

MONDAY (5th).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), St. George's (2 P.M.), St. Mary's (2.30 P.M.), Middlesex (1.30 P.M.), Westminster (2 P.M.), Chelsea (2 P.M.), Samaritan (Gynæcological, by Physicians, 2 P.M.), Soho-square (2 P.M.), City Orthopædic (4 P.M.), Gt. Northern Central (2.30 P.M.), West London (2.30 P.M.), London Throat (9.30 A.M.), Royal Free (2 P.M.), Guy's (1.30 P.M.), Children, Gt. Ormond-street (9 A.M.), St. Mark's (2.30 P.M.).

TUESDAY (6th).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), Guy's (1.30 P.M.), Middlesex (1.30 P.M.), Westminster (2 P.M.), West London (2.30 P.M.), University College (2 P.M.), St. George's (1 P.M.), St. Mary's (1 P.M.), St. Mark's (2.30 P.M.), Cancer (2 P.M.), Metropolitan (2.30 P.M.), London Throat (9.30 A.M.), Samaritan (9.30 A.M. and 2.30 P.M.), Throat, Golden-square (9.30 A.M.), Soho-square (2 P.M.), Chelsea (2 P.M.), Central London Throat and Ear (2 P.M.), Children, Gt. Ormond-street (9 A.M. and 2 P.M.), Ophthalmic (2 P.M.), Tottenham (2.30 P.M.).

WEDNESDAY (7th).—St. Bartholomew's (1.30 P.M.), University College (2 P.M.), Royal Free (2 P.M.), Middlesex (1.30 P.M.), Charing Cross (3 P.M.), St. Thomas's (2 P.M.), London (2 P.M.), King's College (2 P.M.), St. George's (Ophthalmic, 1 P.M.), St. Mary's (2 P.M.), National Orthop[illegible] St. Peter's (2 P.M.), Samaritan (9.30 A.M. and 2.[illegible] (2.30 P.M.), West-minster (2 P.M.), [illegible] Throat (9.30 A.M.), Cancer (2 P.M.), [illegible]), Guy's (1.30 P.M.), Royal Ear (2 P.[illegible].), Children, Gt. [illegible]al, 2 P.M.), Tottenham [illegible].M.).

TH[illegible] P.M.), St. Thomas's [illegible]ring Cross (3 P.M.), St. [illegible]lege (2 P.M.), Middlesex (1.30 P.M.), St. Mary's (2.30 P.M.), Soho-square (2 P.M.), North-West London (2 P.M.), Gt. Northern Central (Gynæcological, 2.30 P.M.), Metropolitan (2.30 P.M.), London Throat (9.30 A.M.), Samaritan (9.30 A.M. and 2.30 P.M.), Throat, Golden-square (9.30 A.M.), Guy's (1.30 P.M.), Royal Orthopædic (9 A.M.), Royal Ear (2 P.M.), Children, Gt. Ormond-street (9 A.M. and 2 P.M.), Tottenham (Gynæcological, 2.30 P.M.), West London (2.30 P.M.).

FRIDAY (9th).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), Guy's (1.30 P.M.), Middlesex (1.30 P.M.), Charing Cross (3 P.M.), St. George's (1 P.M.), King's College (2 P.M.), St. Mary's (2 P.M.), Ophthalmic (10 A.M.), Cancer (2 P.M.), Chelsea (2 P.M.), Gt. Northern Central (2.30 P.M.), West London (2.30 P.M.), London Throat (9.30 A.M.), Samaritan (9.30 A.M. and 2.30 P.M.), Throat, Golden square (9.30 A.M.), City Orthopædic (2.30 P.M.), Soho-square (2 P.M.), Central London Throat and Ear (2 P.M.), Children, Gt. Ormond-street (9 A.M., Aural, 2 P.M.), Tottenham (2.30 P.M.), St. Peter's (2 P.M.).

SATURDAY (10th).—Royal Free (9 A.M.), London (2 P.M.), Middlesex (1.30 P.M.), St. Thomas's (2 P.M.), University College (9.15 A.M.), Charing Cross (2 P.M.), St. George's (1 P.M.), St. Mary's (10 A.M.), Throat, Golden-square (9.30 A.M.), Guy's (1.30 P.M.), Children, Gt. Ormond-street (9 A.M. and 9.30 A.M.), West London (2.30 P.M.).

At the Royal Eye Hospital (2 P.M.), the Royal London Ophthalmic (10 A.M.), the Royal Westminster Ophthalmic (1.30 P.M.), and the Central London Ophthalmic Hospitals operations are performed daily

EDITORIAL NOTICES.

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITOR," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention should be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this office.

Lectures, original articles, and reports should be written on one side of the paper only, AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers—not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale and advertising departments of THE LANCET *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

MANAGER'S NOTICES.

TO SUBSCRIBERS.

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, London, W.C., are dealt with by them? Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid, and *not* to THE LANCET Offices.

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will insure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

THE COLONIAL AND FOREIGN EDITION (printed on thin paper) is published in time to catch the weekly Friday mails to all parts of the world.

The rates of subscriptions, post free, either from THE LANCET Offices or from Agents, are:—

FOR THE UNITED KINGDOM.		TO THE COLONIES AND ABROAD.	
One Year	£1 12 6	One Year	£1 14 8
Six Months	0 16 3	Six Months	0 17 4
Three Months	0 8 2	Three Months	0 8 8

Subscriptions (which may commence at any time) are payable in advance. Cheques and Post Office Orders (crossed "London and Westminster Bank, Westminster Branch") should be made payable to the Manager, Mr. CHARLES GOOD, THE LANCET Offices, 423, Strand, London, W.C.

TO COLONIAL AND FOREIGN SUBSCRIBERS.

SUBSCRIBERS ABROAD ARE PARTICULARLY REQUESTED TO NOTE THE RATES OF SUBSCRIPTIONS GIVEN ABOVE. It has come to the knowledge of the Manager that in some cases higher rates are being charged, on the plea that the heavy weight of THE LANCET necessitates additional postage above the ordinary rate allowed for in the terms of subscriptions. Any demand for increased rates, on this or on any other ground, should be resisted. The Proprietors of THE LANCET have for many years paid, and continue to pay, the whole of the heavy cost of postage on overweight foreign issues; and Agents are authorised to collect, and generally do so collect, from the Proprietors the cost of such extra postage.

The Manager will be pleased to forward copies direct from the Offices to places abroad at the above rates, whatever be the weight of any of the copies so supplied. Address—THE MANAGER, THE LANCET OFFICES, 423, STRAND, LONDON, ENGLAND.

METEOROLOGICAL READINGS.

(Taken daily at 8.30 a.m. by Steward's Instruments.)

THE LANCET Office, Oct. 1st, 1908.

During the week marked copies of the following newspapers have been received:—*Liverpool Daily Post, Ross Gazette, Shields Daily Gazette, Hertfordshire Mercury, Perthshire Advertiser, Ardrossan and Saltcoats Herald, Oxford Times, Referee, Liverpool Courier, Belfast News-Letter, Evening Chronicle (Newcastle-upon-Tyne), Reading Mercury, Dumfries Courier and Herald, Surrey Advertiser, Wimbledon Gazette, &c.*

disease which you should have no difficulty in recalling in the future.

[Sir John Broadbent proceeded to define the various spheres of activity presented by modern medicine, and after forecasting the limitations of the physician's functions which will follow upon the spread of sanitation and the consequent diminution of infective diseases he proceeded :] Sir Almroth Wright will tell us that all that will be left for the physician of the future will be the functions of an opsonist and immunisator. Now I am not so pessimistic, or should I say "opsonistic," as that. I believe that the day will come when Sir Almroth Wright will evolve an anti-rheumatic vaccine which will rob the heart specialist of his livelihood. There will still, however, be left to the physician a host of other maladies which I need not enumerate, and I defy Sir Almroth Wright to discover a vaccine for what I consider one of the most serious disorders of the present day—neurasthenia, or nervous breakdown as I would prefer to call it. By this I do not mean the born-tired feeling of the unemployable or the *blasé* invertebrate condition of the born-rich without occupation, but the loss of nerve control and of mental energy which comes to the neurotic when the nervous system is strained to breaking point, and the hapless sufferer drifts like a ship without a helmsman, storm-tossed on the sea of his emotions. In such case he will look to the physician to assume command and pilot him back to safety. A sympathetic understanding of the symptoms, firmness combined with patience and great tact, will be necessary if the physician is to acquire the confidence of the patient which is essential for the successful conduct of the case. We are, naturally, apt to pay more attention to what we consider "interesting" cases from our point of view, but we must remember that to the patient his own ailment, however trivial we may consider it, is all important. If we bear in mind Bacon's advice[1] on the choice of a physician and regulate our conduct accordingly we shall not, I think, go far wrong. "Physicians are, some of them, so pleasing and conformable to the humour of the patient as they press not the true cure of the disease; and some others are so regular in proceeding according to art for the disease as they respect not sufficiently the condition of the patient. Take one of a middle temper; or if it may not be found in one man, combine two of either sort; and forget not to call as well as the best acquainted with your body, the best reputed of his faculty."

Unfortunately, the tendency of a large section of the British public at the present time is to take no physician at all, but to take some of the secret so-called remedies for every ill that are advertised in such a barefaced manner in the daily press. It is calculated that over two and a half million pounds were spent on this kind of trash during the past year. I think if the medical profession would set to work and see that some legislation is adopted to check the indiscriminate sale of these articles, they would do more good than constantly crying out about hospital abuse by patients who can afford to pay. Personally I have seen very few who could be suspected of coming to my out-patient department under false pretences, and we are at St. Mary's Hospital safeguarded against such abuse by the services of an inquiry officer who investigates the financial position of any doubtful case and refers the patient to a special committee which rejects him if he can afford to pay a doctor. This precaution should be adopted by all hospitals, and I think it would be an excellent thing if there were some coördination of hospitals with neighbouring provident dispensaries, so that cases unsuitable for treatment at the former could be referred to the latter.

[The speaker proceeded to consider certain points in out-patient work which are eminently unsatisfactory from the point of view both of the physician and of the patient. The first of these was the treatment of consumptive patients. He pointed out the frequent inability of such patients to carry out the dietetic and hygienic advice given them in the hospital out-patient department, and described the limited nature of their dwellings and surroundings. He then continued :] You may ask, Why not send these patients to sanatoriums since it is generally recognised that sanatorium treatment offers the best prospects for the arrest and cure of the disease? In the first place many of these cases are too advanced for admission to sanatoriums, as the working man does not usually seek advice till the disease is so advanced that he is too ill to follow his employment; secondly, the sanatorium accommodation for the poor is so inadequate that even if we get an early case the patient may have to wait some four to six months before he can be admitted, by which time the disease will probably be too advanced to allow of his admission. Practically the free sanatorium accommodation for working men in London consists of 100 beds at Northwood, to which admission can only be obtained through the Mount Vernon Hospital, and 100 beds at Frimley Sanatorium, which is attached to the Brompton Hospital for Consumption. There are a certain number of sanatoriums to which patients are admitted for a comparatively small payment, such as the Kelling Sanatorium at Holt (37 beds), the Maltings Sanatorium at Nayland in Suffolk (32 beds), the National Sanatorium at Bournemouth (85 beds), and a few others. In this connexion I must not omit to mention the Sanatorium at Benenden in Kent of 68 beds, which is of especial interest in that it represents the first attempt in this country on the part of the working classes to provide a sanatorium which shall be self-supporting and maintained by their own efforts. This has been carried into effect by the various friendly societies and trade unions, such as the Post Office Union, Hearts of Oak, &c., which have agreed to subsidise beds for the benefit of their members. There are many institutions of this kind in Germany, and it has been found by the working class insurance societies in that country as a matter of experience that it is more economical from their point of view to maintain beds at sanatoriums for their members attacked by pulmonary tuberculosis, many of whom as a result of treatment at the sanatorium for a few months are able to return to work, than to have to dole out sick pay for indefinite periods with no prospect of recovery to their phthisical members. In this country the excellent results obtained at the Frimley Sanatorium by Dr. M. S. Paterson and Dr. A. C. Inman, the former a St. Mary's man, by the scientific methods they employ in utilising the opsonic index as a means of graduating the amount of work which can be safely undertaken by convalescent patients, have shown how the consumptive working man can be restored to a condition of health and bodily vigour such that he can again undertake the most arduous manual labour. It will, however, be many years before the supply of sanatoriums for the poor can possibly equal the demand. In the meantime it is desirable and essential for the proper control of the disease that there should be some coördinated medical and sanitary supervision not only of cases awaiting sanatorium treatment but also of the large number of cases considered too advanced for this. How, then, can this be effected? In Edinburgh, New York, Boston, and other cities in America it has been found that satisfactory and encouraging results in this direction have been attained by tuberculosis dispensaries or clearing houses for consumptives, and I believe that the establishment of a system of similar institutions throughout London working in coöperation with the general hospitals and existing charitable agencies would be the most effectual method of dealing with the tuberculosis question in the metropolis. As a commencement a scheme is now on foot to found an institution of this nature in the borough of Paddington, modelled on the Royal Victoria Dispensary for Tuberculosis which has been working successfully in Edinburgh for the last 21 years. The outlines of the scheme are as follows: That patients should attend regularly at the dispensary. That they should be visited at their homes and instructed as to the proper sanitary precautions to be observed, and that measures should be taken to see that these are effectively carried out. That the coöperation and aid of existing philanthropic agencies and private individuals should be sought to provide for prompt admission of suitable cases to sanatoriums when practicable, and failing this to arrange as far as possible for such patients to live an open-air life. Dr. J. H. Pratt of Baltimore, in an interesting paper read at the meeting of the British Medical Association this year at Sheffield, showed how the open-air treatment of consumption may be effectively carried out even in the homes of the poor, and how by judicious and inexpensive alterations to provide effective ventilation, or by the erection of a balcony or a roof shelter what appear to be utterly unsuitable dwellings can be successfully adapted. The medical supervision of cases discharged from sanatoriums would also form an important part of the work of the institution. It is hoped also that

[1] Essay on the Regimen of Health.

An Address

ON

HOSPITALS; PUBLIC MEDICINE AND MEDICAL STUDIES.

Delivered at the Opening of the Medical Department of Victoria University, Manchester, on Oct. 1st, 1908,

BY SIR T. CLIFFORD ALLBUTT, K.C.B., M.D. CANTAB., HON. D.SC. OXON., F.R.C.P. LOND., F.R.S., &c.,

REGIUS PROFESSOR OF PHYSIC AT THE UNIVERSITY OF CAMBRIDGE, ETC.

GENTLEMEN,—It is one of the noble attributes of the human mind never to rest contented with an achievement, be it never so useful, never so glorious. The old Manchester Infirmary, which happily escaped the division so injurious to some other hospitals, was as famous in its great physicians and surgeons, and in its generous and enlightened benefactors, as in form it was stately and in its history monumental. Yet the mind of your citizens, thankful as they have been for a great past, would not rest contented on form and history; gazing still insatiably into the future, contemplating the new scope and potencies of modern medicine, both personal and national, reading the principles on which this progress had been, and is being, made, and the signals of these ever-widening ranges of knowledge, power, and beneficence, Manchester men, in alliance with their University, are inspired to build yet more stately, to endow more richly, and thus to organise that still vaster compass of charity, of learning, and of municipal and national efficiency which I have visited and to which I have the great honour of bearing witness to-day. Thankful, nevertheless, as I have said, for a great past; but while these words are passing my lips the most ardent pilgrim will pause, for a moment as, in the visions of his memory, are reflected the figures of those strong companions who so lately were breasting the hill with us, but whose hands are now dropped and whose familiar and prophetic voices are fallen into silence. Manchester and Manchester University, even after the loss of such men as Leech, Dreschfeld, Harris, Ashby, Cullingworth, Jones, Collier, will be more and more; notwithstanding we are haunted by the pathos of human life and death, wherein they, who of all of us knew best how to rejoice in your new hopes and new promises, have lately been taken from us; and we are left to rejoice, if by no means alone, yet without their wise counsels, without the enthusiasm of their presence. And yet I repeat "by no means alone." It is indeed the older men, such as he who now addresses you, who see most vividly, and feel most keenly, that the fountains of life ever renewed, and of progress reinforced and accelerated, have their springs not in our generation but in the bands of eager young men whom year by year and day by day your University bears in its pride. And if sometimes in their naughtiness these ardent youths are inwardly disposed to scorn our ingatherings, to despise our experience, and even to hold our wisdom in suspicion,—well, it is better than if they had fed themselves with our formulas and fondled our idols. Social development has always been discontinuous, and a succession of slightly explosive generations is better than the alternative of revolution, of catastrophe by longer accumulation of pent-up stresses.

HOSPITAL MANAGEMENT.

Permit me on the threshold of this new infirmary to make a few remarks on hospital purposes and management. Of the management of the Manchester Infirmary I know nothing, and under this head no word of mine can be charged with censure or innuendo. I speak generally when I say that a prevailing error in hospital government is the failure of the lay managers to act in frank and equal partnership with the medical managers, whereby the full coöperation and best results of money and knowledge are more or less sacrificed, the machine runs with needless friction, and occasionally jams. In this matter the lay governor is a little apt to be arrogant, a little purse-proud. Yet, after all, money is but the raw material, to be worked up with knowledge. Upon a hospital board laymen, even wealthy laymen, may come and go and be noted of no man; whereas such changes in the hospital medical staff would be promptly disastrous, for the layman's hospital is a stationary hospital.

That money is of more value than knowledge is a vulgar and erroneous notion; yet in our partnership too often the lay manager presumes that the physician or surgeon is at the hospital not his partner but in some sort his servant. Occasionally indeed he is ungenerous enough to depreciate the equal benevolence of the medical services on the ground that if unsalaried they "pay" in profit and reputation. But do we find that in other professions public officers—as a clerk to justices, for instance, as a solicitor to a great banking company, as a consulting engineer or chemist to gas or water works—are unsalaried, because the office carries with it opportunities, reputation, and fees! By no means. The other day I asked a distinguished physician and a distinguished surgeon on the staffs of two leading London hospitals if it paid them, however indirectly, to devote thus their priceless services for the sick and for the raising up of successors like themselves? They answered almost in the same words, "The time I give to the hospital costs me 20 or 30 guineas a week"—surely a more than ample pecuniary recompense for any promotion in earlier years. Moreover, even in London, and more generally in the provinces, a man of parts and address, starting independently of a hospital, has opportunities of material gain on the average as good as, and quicker in return than, those of his fellow student who, more disdainful of commercial balances, at the hospital devotes himself in the first instance to science and charity. Yet it is on these men that the virtues and the honours of a great hospital chiefly depend.

Let us put it more plainly; a layman, with a purse in his hand, and a physician stand on either side of the bed of a sick man. The layman offers to spend £5 on the patient if the physician of his learning and benevolence will convert this cash into means of solace and cure. Neither partner is of much use to the sick man without the other. The man with the banknote cannot, it is true, allow the physician to spend the money uncontrolled; but, on the other hand, without the physician his money would be wasted. The partners, then, are not master and servant, but comrades; and if with many banknotes and many patients a great healing engine is created, the principle of frank and equal partnership is not modified. If the expert, after the manner of experts, is prone sometimes to forget the relative proportions of things, to push ideas beyond the limits of common sense, to be importunate, or even extravagant, the layman on his side is as prone to be domineering, meddlesome, and short-sighted. Everything in the healing machine costs money, and the layman must regard the ultimate economy of it; but as everything in it is also therapeutical whatsoever he may do or avoid affects more or less directly the treatment of the patients; whether it be, let us say, the heating and ventilation, the decoration of the walls, or even the baking of the bread and the quality of the blankets. Unless, then, the lay manager keep incessantly in touch with the medical he will continually make little mistakes and large blunders. Now do we, generally speaking, find this broad and continuous counsel between these partners in large hospitals? Do we not too often find on the contrary a lay board shutting itself up by itself, and week by week proceeding to business without conference with the honorary staff; acting, indeed, sometimes as if the staff existed only to do what it is told; a custom surely discourteous as well as mischievous to the business the two partners have at heart. How, then, should concord, mutual understanding, and harmonious and efficient coöperation be maintained? At Leeds every member of the honorary staff is, *ex-officio*, a member of the weekly board; thus at every board one or other of the staff is sure to be present; so that if any innocent-looking proposal be made which in so complex a machine might react prejudicially upon the welfare of the sick, a warning note is heard, and the proposal is deferred or modified. Larger issues are discussed, on due notice, by full boards of lay and medical members, with frank and equal interchange of opinion; but the staff vote is properly limited,—in my day to eight, the eight votes being readily distributed among the staff at the discretion of the members present; votes being, of course, allotted first to the members of any special department chiefly concerned in the issue. The result during my experience was that no cool breezes

In all seriousness, however, let me now beg you to give your undivided attention to the cell in its manifold variations of form and power; here in this microcosm you shall find sufficient to engage and satisfy all your cravings for learning. Let me insist further that not only medicine but surgery also are both equally dependent upon the good pleasure of our structural unit, for what good purpose would it serve to bring the broken ends of the bone together if the osteoplastic cell failed to exert its powers? why tie, twist, or seal the artery with the cautery unless you can count upon the tissue cell to make good the ligation, torsion, or cauterisation? wherefore the delicate plastic operation except in reliance upon the plastic properties of the cell? It is manifest this corpusculum has an importance disproportionate to its size and the question how we may influence it becomes of great consequence. Look at it as there it trails a pseudopodium or brandishes a cilium or otherwise exhibits the fundamental property of contractility; or again there as it incorporates the simpler molecule and builds it up into some higher form of synthesis, or, reversing the process, breaks down the absorbed molecule into some simple grouping—in other words, as it builds up the internal secretion in the one case, prepares the excretory product in the other; again, see it as it busies itself storing potential energy in its substance with a view to its becoming dynamic at the right moment. Now all these activities depend upon processes which, being intracellular, intermolecular, are minute. How shall they be influenced, supposing them to fail in vigour or to become perverted?—by knife, or forceps, or other surgical engine? This is not conceivable; only by processes not less minute than their own, processes which can find room for their working within the body of the cell, only thus can they be reached. But these processes in request are none other than those we term physicochemical and they are just such as the materia medica presents. The theory is unexceptionable. The medicamenta should be by nature eligible for the purpose indicated; but what says the ounce of practice which proverbially outweighs the ton of conjecture? For the answer I will refer you to the surgeon, ask him for his opinion as to the value of the mercurial, the iodide, the antiseptic. If he allow their value the whole case of the utilisability of the drug, its legitimate sphere of action, is established. Of course, such admission proves nothing as to the value of this or that particular drug, neither does it lend countenance to indiscriminate drugging, just as little as the wise operation justifies the injudicious one, in particular, or a meddlesome surgery, in general. [The lecturer illustrated this point by a eulogy of Lord Lister's employment of antiseptics.] You must next proceed to the medicamenta, and here you must be very searching in your investigation of what they claim to do and of the explanations which they proffer of their usefulness; do not, however, be too exacting in your demand for a reason; considering the complexity of the problem this were unreasonable, therefore unscientific. The only right course is upon sufficient evidence to act and *make trial.*

[Dr. Sainsbury proceeded to guard his remarks by a warning against the indiscriminate use of drugs and laid much of the blame for it upon the public love of "a prescription." He insisted that treatment by drugs should always be subordinate to treatment dietetic and hygienic and proceeded:—] And now I want to pass to another matter and must ask you to look at the cell unit as it may happen to be contracting or secreting or otherwise functioning. In the midst of this business suddenly by way of a nerve fibre comes a something and we note one of two things, either that the business of the cell goes on at an increased pace or that it begins to slacken, proceeding even to a complete standstill. What has taken place? Force of some kind must have been conveyed by the nerve fibre, for the momentum of the cell has been added to or taken from, but how exactly the exciting or inhibiting dose of energy has been brought to bear this is a more secret matter. Attractive as is this question I may not stay to inquire into it, for indeed it has been mentioned only for the purpose of insisting that after this very fashion works that obscure power which we call the mind. What the mechanism of conveyance and application may be, however concealed the route, the fact is unquestionable that the mind influences the body, now quickening, now depressing the vitality of the cell. By the mind we understand the intellectual faculties, but there is another side to the subjectivity of man—viz., the emotional or affective—and these influence even more powerfully cell activity. How? Here is a great mystery, but again the fact is certain—the psyche is a great moving element in what we are pleased to regard as the lower planes of life, the bodily workings. But does this bear upon the medical curriculum? It does indeed, nor must you ever lose sight of it. If the working of the cell is subject to the mental and emotional factor, then the psychology of man becomes a study of direct and supreme interest for you. Henceforth it becomes yours to enlist that psychology into the medical service of the body, yours to learn how that may be done. Now for one thing to touch another it must have affinity, must be in sympathy with it, and hence since the psychology of one man will be in closest relationship with the psychology of another, it follows that by psychic influences you will impress most readily the inner man. Do not, therefore, forget your own psyche, cultivate it, let it grow; expansion, by giving it a larger periphery, will cause it to present a larger surface for contact with other subjectivities and thus will enlarge the scope of your influence upon your fellows. Do not imagine that this is sentimentalism; sentiment it is, I admit, but whereas sentimentalism is a mere affectation, sentiment is a very real thing and you must not let it go, as much for your own sakes as also for the sake of those others whose minds and bodies you will be able to influence thereby. These things you may not be able to weigh, but believe me they have weight. The trouble, however, is that the practical business of life, in your case the medical curriculum for the next five years, is often so engrossing that it tends to monopolise the attention and to leave no room for studies and recreations which stand outside the line of its strong compelling current. What shall you do? You must fight against this compulsion, and thus—let us suppose that in your progress so far you have acquired an interest in poetry, in art, in music, to consider only the æsthetic side of the psyche—well, you must keep these interests alive. To do this you need not fear that time will be lacking; it will not be necessary to devote yourselves in excess to the culture of the æsthetic, a small attention will suffice; give that attention. [*In illustration of this point the lecturer quoted Charles Darwin's lamentation over the atrophy of his æsthetic sense in the pursuit of science.*]

The æsthetic aspect of man does not reveal to us the whole of his humanity; there is, besides, the ethical aspect and the religious aspect, both calling aloud for consideration by the physician, both standing for much more than the æsthetic in the standardisation of character; but though this is so I may only remind you that these aspects of humanity cover forces of immense potential which, for your own sakes as well as for the sake of others, you cannot afford to ignore; forces, moreover, which are subject to the great law of growth with use, of atrophy with disuse. Give this whole subject your very earnest consideration and endeavour by the development of your own psychic powers to the best of your ability to have as much as possible in common with your fellows; this will apply not merely to the five years' curriculum but to your work, the pursuit of medicine, throughout life.

MIDDLESEX HOSPITAL.

INTRODUCTORY ADDRESS BY A. M. KELLAS, PH.D., B.SC., LECTURER IN CHEMISTRY.

Dr. Kellas in his opening words welcomed Mr. Rudyard Kipling and the other guests of the school and also the new students, to whom he commended the motto "Labor Omnia Vincit." He proceeded to announce the title of his discourse as "A Glance at the Development of Medicine as a Science." He passed rapidly in review the salient events in the history of medicine in the early ages of the world and in classical times, dwelling especially on the doctrines of Hippocrates and Galen; he then spoke briefly of the Arabian physicians and pointed out the influence of Arabian upon European medicine in the Middle Ages, illustrating it by the work of Avicenna, Paracelsus, and others. He then passed on to Ambroise Paré and after describing William Harvey's discovery of the circulation of the blood he continued:

Contemporary with Harvey there flourished an iatrochemical school founded by a famous professor at Leyden called Sylvius (1614–1672) who attempted to form a system of medicine depending upon the current views in chemistry and the circulation of the blood. Fermentations took place in the body and might produce acids which caused fever and other diseases. The most distinguished disciple of Sylvius

ON

HOSPITALS; PUBLIC MEDICINE AND MEDICAL STUDIES.

Delivered at the Opening of the Medical Department of Victoria University, Manchester, on Oct. 1st, 1908,

BY SIR T. CLIFFORD ALLBUTT, K.C.B.,
M.D. CANTAB., HON. D.SC. OXON., F.R.C.P.
LOND., F.R.S., &c.,

REGIUS PROFESSOR OF PHYSIC AT THE UNIVERSITY OF CAMBRIDGE, ETC.

GENTLEMEN,—It is one of the noble attributes of the human mind never to rest contented with an achievement, be it never so useful, never *so glorious*. The old Manchester Infirmary, which happily escaped the division so injurious to some other hospitals, was as famous in its great physicians and surgeons, and in its generous and enlightened benefactors, as in form it was stately and in its history monumental. Yet the mind of your citizens, thankful as they have been for a great past, would not rest contented on form and history; gazing still insatiably into the future, contemplating the new scope and potencies of modern medicine, both personal and national, reading the principles on which this progress had been, and is being, made, and the signals of these ever-widening ranges of knowledge, power, and beneficence, Manchester men, in alliance with their University, are inspired to build yet more stately, to endow more richly, and thus to organise that still vaster compass of charity, of learning, and of municipal and national efficiency which I have visited and to which I have the great honour of bearing witness to-day. Thankful, nevertheless, as I have said, for a great past; but while these words are passing my lips the most ardent pilgrim will pause for a moment as, in the visions of his memory, are reflected the figures of those strong companions who so lately were breasting the hill with us, but whose hands are now dropped and whose familiar and prophetic voices are fallen into silence. Manchester and Manchester University, even after the loss of such men as Leech, Dreschfeld, Harris, Ashby, Cullingworth, Jones, Collier, will be more and more; notwithstanding we are haunted by the pat*hos of* human life and death, wherein they, who of all of us knew best how to rejoice in your new hopes and new promises, have lately been taken from us; *and we are* left to rejoice, if by no means alone, yet without their wise counsels, without the enthusiasm of their presence. And yet I repeat "by no means alone." It is indeed the older men, such as he who now addresses you, who see most vividly, and *feel* most keenly, *that* the fountains of life ever renewed, and of progress reinforced and accelerated, have their springs not in our generation but in the *bands of* eager young men whom year by year and day by day your University bears in its pride. And if sometimes in their naughtiness these ardent youths are inwardly disposed to scorn our ingatherings, to despise our experience, and even to hold our wis*dom in* suspicion,—well, *it is* better than if they had fed themselves with our formulas and fondled our idols. Social development has always been discontinuous, and a succession of slightly explosive generations is better than the alternative of revolution, of catastrophe by longer accumulation of pent-up stresses.

HOSPITAL MANAGEMENT.

Permit me *on the* threshold of this new infirmary to make a few remarks on hospital purposes and management. Of the management of the Manchester *Infirmary* I know nothing, and under this head no word of mine can be charged with censure or innuendo. I speak generally when I say that a prevailing error in hospital government is the failure of the lay managers to act in frank and equal partnership with *the* medical managers, whereby the full coöperation and best results of money and knowledge are more or less sacrificed, the machine runs with needless fric*tion*, and occasionally jams. *In this* matter the lay governor is a little apt to be arrogant, a little purse-proud. Yet, after all, money is but the raw material, to be worked up with knowledge. Upon a hospital board laymen, even wealthy laymen, may come and go and be *noted of no man*; whereas such changes in the hospital *medical* staff would be promptly disastrous, for the layman's hospital is a stationary hospital.

That money is of more value than knowledge is a vulgar and erroneous notion; yet in our partnership too often the lay manager presumes that the physician or surgeon is at the hospital not his partner but in some sort his servant. Occasionally indeed he is ungenerous enough to depreciate the equal benevolence of the medical services on the ground that if unsalaried they "pay" in profit and reputation. But do we find that in other professions public officers—as a clerk to justices, for instance, as a solicitor to a great banking company, as a consulting engineer or chemist to gas or water works—are unsalaried, because the office carries with it opportunities, reputation, and fees! By no means. The other day I asked a distinguished physician and a distinguished surgeon on the staffs of two leading London hospitals if it paid them, however indirectly, to devote thus their priceless services for the sick and for the raising up of successors like themselves! They answered almost in the same words, "The time I give to the hospital costs me 20 or 30 guineas a week"—surely a more than ample pecuniary recompense for any promotion in earlier years. Moreover, even in *London*, and *more generally* in the provinces, a man of parts and address, starting independently of a hospital, has opportunities of material gain on the average as good as, and quicker in return than, those of his fellow student who, more disdainful of commercial balances, at the hospital devotes himself in the first instance to science and charity. Yet it is on these men that the virtues and the honours of a great hospital chiefly depend.

Let us put it more plainly; a layman, with a purse in his hand, and a *physician stand on either side of the bed of a* sick man. The layman offers to spend £5 on the patient if the physician of his learning and benevolence will convert this cash into means of solace and cure. Neither partner is of much use to the sick man without the other. The man with the banknote cannot, it is true, allow the physician to spend the money uncontrolled; *but, on the other hand*, without the physician his money would be wasted. The partners, then, are not master and servant, but comrades; and if with many banknotes and *many patients* a great healing engine is created, the principle of frank and equal partnership is not modified. If the expert, after the manner of experts, is prone sometimes to forget the relative proportions of things, to push ideas beyond the limits of common sense, to be importunate, or even extravagant, the layman on his side is as prone to be domineering, meddlesome, and *short-sighted*. *Everything* in the healing machine costs money, and the layman must regard the ultimate economy *of it*; but *as* everything in it is also therapeutical whatsoever he may do or avoid affects *more* or less directly the treatment of the patients; whether it be, let us say, the heating and ventilation, the decoration of the walls, or even the baking of the bread and the quality *of the* blankets. *Unless, then*, the *lay* manager keep incessantly in touch with the medical he will continually make little mistakes and large blunders. Now do we, generally speaking, find this broad and continuous counsel between these partners in large hospitals? Do we not too often find on the contrary a lay board shutting itself up by itself, and week by week proceeding to business without *conference with the honorary staff*; acting, indeed, sometimes as if the staff existed only to do what it is told; a *custom* surely discourteous as well as *mischievous* to the business the two partners have at heart. How, then, should concord, mutual understanding, and harmonious and efficient coöperation be maintained? At Leeds every member of the honorary staff is, *ex-officio*, a member of the weekly board; *thus at every board* one or other of the staff is sure to be present; so that if any innocent-looking proposal be made which in so complex a machine might react prejudicially upon the welfare of the *sick*, a warning note is heard, and the proposal is deferred or modified. Larger issues are discussed, on due notice, by full boards of lay and medical members, with frank and equal interchange of opinion; but the *staff vote* is properly limited,—in my day to eight, the eight votes being readily distributed among the staff at the discretion of the members present; votes being, of course, allotted first to the members of any special department chiefly concerned in the issue. The result *during* my experience was that no cool breezes

No. 4441.

frequency current, and the Finsen light can merely be mentioned. Bacteriology and Protozoology must be passed over. One cannot refrain from mentioning a most successful piece of work carried out during this year by one of the staff of this hospital in connexion with cancer. He has discovered how to obviate the terrible effects caused by a blocking of the axillary lymph spaces and ducts by cancer growth in long-standing cases.

[The lecturer then said a few words regarding the development of preventive medicine, and concluded with some remarks upon recent applications of chemistry to medicine.]

A division of chemical medicine which has risen into prominence during the last ten years is the "ionic" system of treatment, which aims at introducing curative elements where required by means of passage of an electric current through the body. Many interesting cures have been effected, the current being even applied to the brain. Many patients treated with the current through the brain assert that it clears their ideas, and one lady felt so much better mentally that she insisted upon her husband taking the treatment in order to improve his faculties. The precedent seems dangerous. Work in connexion with the new "ionic" treatment is being carried out in the Cancer Research Laboratories and Electrical Department of this hospital.

And now, in order to show the nature of the work to be done in chemical physiology and chemical pathology, one might perhaps be excused for entering into a few technical details. The human body is made up of microscopic living structures called cells, which contain many different chemical substances—e.g., a drop of blood contains about 5,000,000 living cells floating in blood serum, and for simplicity we will confine ourselves to substances present in the blood. The chemical compounds present are generally extraordinarily complex, consisting chiefly of bodies called proteins. Some simple substances are also present, two of small complexity, being water and sodium chloride. Now, before we can understand the chemical changes taking place in the human body our knowledge of proteins must be greatly increased. The proteins must be split up and the percentages of the different decomposition products formed must be accurately estimated for each. The methods of building up the proteins artificially from these parts must then be worked out. Two of the most important substances present in blood are serum albumin and hæmoglobin. The probable chemical formulæ of these substances are $C_{450}H_{720}N_{116}S_6O_{140}$ and $C_{758}H_{1203}N_{195}O_{218}FeS_3$. The relative numbers of atoms present (1432, 2378, 3, and 2 respectively) give a vague idea of the relative complexities but not of the relative difficulties of investigation. The difficulties increase out of all proportion to relative numbers of atoms present. A few decomposition products of serum albumin and hæmoglobin are histidin ($C_6H_9N_3O_2$), leucin ($C_6H_{13}NO_2$), and tyrosine ($C_9H_{11}NO_3$). So far as yet investigated hæmoglobin probably contains 36 residues of leucin molecules, 12 residues from histidin molecules, along with residues from tyrosine, arginin, cystin, and many other components. The chemical constitutions of the decomposition products and also of synthetic substances formed from them must be completely worked out. The difficulties which must be surmounted are extraordinary.

This completes the brief and inadequate glance at the development of medicine as a science. It has been shown that chemical pathology and chemical physiology are advancing comparatively slowly, because of the great difficulties inherent in these subjects, and that this fact delays the development of medicine. It was stated in the introduction to this address that continuous work would be required to surmount the difficulties. One would venture to suggest that continuity of effort could readily be attained by the endowment of several professorships or lectureships in the subjects named. (I hasten to add that I am not remotely eligible for such appointments.) The cost would be moderate. If the salaries of lecturers were £500, rising to £800 per annum, £1000 per annum would cover the cost for each post endowed, and one cannot doubt that the effect upon the development of medicine would be far-reaching. Young medical men who were ready to undergo a thorough training in analytical chemistry, and prepared to make the subject their life's work, would alone be eligible. One might expect that a State which can afford £65,000,000 for army and navy and £6,000,000 for old age pensions would not hesitate to endow at the small cost mentioned professorships in medicine which would have world-wide influence of a beneficial nature. Unfortunately our statesmen are most parsimonious towards any learning except primary education. Professor Starling, in a recent oration at University College on the "Building of a University," sums up their position as follows: "The attitude of our Government to a University is that of a gentleman who is asked for a copper by a tramp on the high road. They do indeed throw us a trifling dole, but take care to couple with the gift the statement that we have no right whatever to the money." At present very little work of the nature indicated is being done in this country, there being only one professorship of chemical pathology here. A considerable quantity of work is carried out in Germany which is to the front in scientific matters. If the State will not move in such a matter we must await the generosity of individuals. In the sketch of medical development just given the work of members of the Middlesex Hospital staff has been repeatedly mentioned, and we wish to emphasise the fact that a hospital which has been connected with William Hunter, Sir Charles Bell, Campbell de Morgan, and other eminent medical men of the very first rank whom exigencies of time have prevented one from mentioning, such as Sir Erasmus Wilson, Sir Thomas Watson, Sir William Flower, and Sir J. Burdon Sanderson, has traditions of a very high order, which should incite both to study with a view to excel in the profession and a desire to promote the progress of medical science. That the hospital is to-day abreast of its highest traditions you must admit, when I mention that among honours held by its present staff are the following: Sir Richard Douglas Powell is President of the Royal College of Physicians of London, Mr. Henry Morris is President of the Royal College of Surgeons of England, and Dr. J. Kingston Fowler is Dean of the Faculty of Medicine of the University of London.

A CASE OF DIVISION OF THE AUDITORY NERVE FOR PAINFUL TINNITUS.

By CHARLES A. BALLANCE, M.V.O., M.S. LOND., F.R.C.S. ENG.,

SURGEON TO, AND LECTURER ON SURGERY AT, ST. THOMAS'S HOSPITAL.

A WOMAN, aged 49 years, was sent to me by Mr. W. G. Sutcliffe of Margate on Nov. 14th, 1906. Her illness commenced suddenly in February, 1906, with buzzing tinnitus, vertigo, and nausea, and on several subsequent occasions a similar attack occurred. After a time the tinnitus became continuous and was more and more often accompanied by giddiness. No benefit was derived from medical treatment nor from staying at Margate and the Isle of Wight. In September, 1906, the character of the tinnitus suddenly changed from a buzzing to a most distressing steaming or whistling noise which, at its height, became actually painful; the patient's own expression was "the noise is the pain." When I saw her on Nov. 14th, 1906, about ten months after the commencement of the illness, she complained of intolerable tinnitus in the right ear, occasionally accompanied by giddiness and nausea. She was in great distress and feared that if no relief could be given she would go mad and kill herself. The right ear was almost totally deaf; the watch and the voice were not heard at all and the tuning fork was scarcely perceived. The tympanic membrane looked normal. There were no signs of a gross intracranial lesion; the disease was clearly labyrinthine. I suggested division of the auditory nerve but advised the

Social development has always been discontinuous, and a succession of slightly explosive generations is better than the alternative of revolution, of catastrophe by longer accumulation of pent-up stresses.

HOSPITAL MANAGEMENT.

Permit me on the threshold of this new infirmary to make a few remarks on hospital purposes and management. Of the management of the Manchester Infirmary I know nothing, and under this head no word of mine can be charged with censure or innuendo. I speak generally when I say that a prevailing error in hospital government is the failure of the lay managers to act in frank and equal partnership with the medical managers, whereby the full coöperation and best results of money and knowledge are more or less sacrificed, the machine runs with needless friction, and occasionally jams. In this matter the lay governor is a little apt to be arrogant, a little purse-proud. Yet, after all, money is but the raw material, to be worked up with knowledge. Upon a hospital board laymen, even wealthy laymen, may come and go and be noted of no man; whereas such changes in the hospital medical staff would be promptly disastrous, for the layman's hospital is a stationary hospital.

That money is of more value than knowledge is a vulgar and erroneous notion; yet in our partnership too often the lay manager presumes that the physician or surgeon is at the hospital not his partner but in some sort his servant. Occasionally indeed he is ungenerous enough to depreciate the equal benevolence of the medical services on the ground that if unsalaried they "pay" in profit and reputation. But do we find that in other professions public officers—as a clerk to justices, for instance, as a solicitor to a great banking company, as a consulting engineer or chemist to gas or water works—are unsalaried, because the office carries with it opportunities, reputation, and fees! By no means. The other day I asked a distinguished physician and a distinguished surgeon on the staffs of two leading London hospitals if it paid them, however indirectly, to devote thus their priceless services for the sick and for the raising up of successors like themselves? They answered almost in the same words, "The time I give to the hospital costs me 20 or 30 guineas a week"—surely a more than ample pecuniary recompense for any promotion in earlier years. Moreover, even in London, and more generally in the provinces, a man of parts and address, starting independently of a hospital, has opportunities of material gain on the average as good as, and quicker in return than, those of his fellow student who, more disdainful of commercial balances, at the hospital devotes himself in the first instance to science and charity. Yet it is on these men that the virtues and the honours of a great hospital chiefly depend.

Let us put it more plainly; a layman, with a purse in his hand, and a physician stand on either side of the bed of a sick man. The layman offers to spend £5 on the patient if the physician of his learning and benevolence will convert this cash into means of solace and cure. Neither partner is of much use to the sick man without the other. The man with the banknote cannot, it is true, allow the physician to spend the money uncontrolled; but, on the other hand, without the physician his money would be wasted The partners, then, are not master and servant, but comrades; and if with many banknotes and many patients a great healing engine is created, the principle of frank and equal partnership is not modified. If the expert, after the manner of experts, is prone sometimes to forget the relative proportions of things, to push ideas beyond the limits of common sense, to be importunate, or even extravagant, the layman on his side is as prone to be domineering, meddlesome, and short-sighted. Everything in the healing machine costs money, and the layman must regard the ultimate economy of it; but as everything in it is also therapeutical whatsoever he may do or avoid affects more or less directly the treatment of the patients; whether it be, let us say, the heating and ventilation, the decoration of the walls, or even the baking of the bread and the quality of the blankets. Unless, then, the lay manager keep incessantly in touch with the medical he will continually make little mistakes and large blunders. Now do we, generally speaking, find this broad and continuous counsel between these partners in large hospitals? Do we not too often find on the contrary a lay board shutting itself up by itself, and week by week proceeding to business without conference with the honorary staff; acting, indeed, sometimes as if the staff existed only to do what it is told; a custom surely discourteous as well as mischievous to the business the two partners have at heart. How, then, should concord, mutual understanding, and harmonious and efficient coöperation be maintained? At Leeds every member of the honorary staff is, *ex-officio*, a member of the weekly board; thus at every board one or other of the staff is sure to be present; so that if any innocent-looking proposal be made which in so complex a machine might react prejudicially upon the welfare of the sick, a warning note is heard, and the proposal is deferred or modified. Larger issues are discussed, on due notice, by full boards of lay and medical members, with frank and equal interchange of opinion; but the staff vote is properly limited,—in my day to eight, the eight votes being readily distributed among the staff at the discretion of the members present; votes being, of course, allotted first to the members of any special department chiefly concerned in the issue. The result during my experience was that no cool breezes patient first to consult Dr. D. Ferrier. I did not see her again until January, 1908, when she came to me with Dr. Soden. In the interval she had been under Dr. Ferrier, Dr. Purves Stewart, Mr. Lake, Mr. Woods, and others. Many methods of treatment, including hypnotism and high-frequency currents, had been tried. In November, 1907, Mr. Lake removed the semicircular canals of the affected side; this operation almost completely relieved the patient from the vertigo but in no way affected the painful tinnitus. Facial palsy followed Mr. Lake's operation but from this there were signs of commencing recovery. The general condition was not good; the patient was feeble, fat, and flabby, and the pulse, for some reason or another, varied from 100 to 120. I renewed my original suggestion that the auditory nerve should be divided and this was now agreed to by Dr. Ferrier.

On Jan. 18th, 1908, bone was removed over the right cerebellar region, and nine days later the operation was completed. The dura was opened and the cerebellar hemisphere displaced backwards and inwards by marine sponge pressure. On removing the sponges the cerebellum remained in the retracted position, so that the fifth, seventh, eighth, ninth, tenth, eleventh, and twelfth nerves were exposed to view (see figure). The eighth nerve was depressed so as to enable me to see clearly the rounded cord of the facial nerve and to avoid injuring it when dividing the auditory nerve. Then the division of the auditory nerve was easily accomplished. I made no attempt to separate the nerve of Wrisberg from the auditory nerve; indeed, I did not see it, no doubt because it was concealed by the arachnoid sheath. There was slight hæmorrhage from the auditory artery. On recovery from the anæsthetic there was conjugate deviation of the eyes to the left, and the eyes could not be moved towards the right. In about 48 hours this movement was again possible, but was feeble and was attended by lateral nystagmus with wide excursions. Convalescence was very slow, the pulse remained at 100, or over, for some weeks, and there was a little difficulty in swallowing due to paresis of the right side of the palate and of the right side of the pharynx. There were occasional syncopal attacks and also paroxysmal feelings of impending suffocation by which she was sometimes awakened at night. There was absolute deafness of the right ear. The facial palsy was not increased by the operation. On March 13th there was still slight paresis affecting the right side of the palate and pharynx. Nystagmus was still present. The optic discs were normal and the pupils were equal. The respirations were 22 and feeble. The pulse was 100 and regular. The heart was normal. There was neither anæsthesia nor ataxia. The plantar reflexes were flexor. I saw the patient again on May 24th. The scalp flap was concave. *The painful tinnitus had ceased.* There was still some weakness on the right side of the face. The tongue deviated very slightly to the left when protruded. There was nystagmus when looking to the right but less than formerly, and only slight jerks on looking to the left. The palate, pharynx, and vocal cords moved normally and there was no longer any difficulty in breathing or in swallowing. The sense of taste was lost along the right side of the tongue. There was an area of deficient sensation (as tested with a camel's hair brush) of about the size of a split pea at the junction of the middle of the posterior border of the right external meatus with the concha. There was no affection of any other cranial nerve. The knee- and ankle-jerks were greater on the right than on the left side. The supinator jerks were equal. The pulse was 60. There were no indications of gross disease and no apparent reason why the patient should not get quite well.

Attempts to divide the auditory nerve have been previously made, but I am not aware that the operation I have just described was employed in any of them. It presented no difficulty; by the use of marine sponge pressure the nerves were clearly exposed and the view was not obscured by blood or cerebro-spinal fluid. I learnt this method from Dr. Ferrier, who employed it with great success in his experiments on the monkey's brain. I think it could often be used with great advantage in preference to the metal retractor when we have to displace the brain in order to divide a cranial nerve or remove a deeply seated tumour, such as one situated in the cerebello-pontine angle or one growing from the pituitary body.

The operation of division of the auditory nerve is a means of relieving a patient from distressing tinnitus and vertigo not amenable to other measures. Such patients are almost invariably deaf on the affected side so that no sacrifice is made by cutting off the labyrinth from its connexion with the brain. The operation being undertaken for disease of the labyrinth or its ganglia does not give rise to that group of symptoms which follows division of the auditory nerve or extirpation of the labyrinth in animals so well described by Bechterew and Risien Russell. Mr. Lake's skilful operation for removing the semicircular canals cannot be expected to relieve a painful tinnitus. Either the cochlear ganglion must be destroyed or the cochlear division of the auditory nerve divided.

Further successful cases would afford opportunities of correcting or confirming the views which have been expressed as to the course of the nerve fibres transmitting impulses of taste. Such opportunities would be of especial value since the sense of taste cannot be satisfactorily tested in the lower animals. At the operation several cranial nerves were so clearly exposed that I determined to recognise each one by stimulation. The fifth, seventh, ninth, tenth, eleventh, and twelfth nerves were stimulated both mechanically and electrically. The muscles of mastication, supplied by the motor division of the fifth; the muscles of the face, supplied by the seventh; the sterno-mastoid and trapezius, supplied by the eleventh; and the muscles of the tongue, supplied by the twelfth; all contracted. The glosso-pharyngeal and the vagus were stimulated but the results were not observed as the larynx, pharynx, and palate were not seen. No alteration in the pulse-rate or in the respiratory movements was detected. The nerve of Wrisberg was divided with the auditory in the case here related, and the sense of taste was lost on the corresponding side of the tongue, not only in the anterior two-thirds but also in the posterior third, which is usually considered to depend upon the glosso-pharyngeal for its connexion with the brain. Should it be found possible to divide the auditory nerve without injury to the nerve of Wrisberg we should expect the sense of taste to remain unaffected.

It is well known that when the chorda tympani, or the facial trunk above the point where the chorda tympani is given off is paralysed the sense of taste is lost on the anterior two-thirds of the tongue on the same side. In the complete mastoid operation the chorda tympani nerve can seldom escape injury and may be paralysed by disease before the operation. I have tested the sense of taste in a few patients after their recovery from the mastoid operation and found that it was lost on the anterior two-thirds of the tongue. Unfortunately the sense of taste was not tested in my case prior to division of the auditory nerve and the nerve of Wrisberg. It must have been already lost on the anterior two-thirds of the tongue owing to the facial palsy, but there is no reason to suggest that it was lost on the posterior third of the tongue.

The facial nerve and the nerve of Wrisberg together form a mixed nerve comparable to a spinal nerve; the motor impulses pass by way of the facial and the sensory by way of the nerve of Wrisberg. The fibres connected with the unipolar cells of the geniculate ganglion, both proximally and distally, convey impulses towards the brain; the ganglion itself being the so-called ganglion of origin or trophic centre of the sensory root of the seventh nerve, just as the ganglion on a spinal root is the trophic centre of the sensory portion of a spinal nerve. The sensory portion contains special sense fibres from the taste organs of the tongue and trophic and sensory fibres from the skin of the external meatus and concha, but the precise extent of the peripheral area from which it transmits impulses is not yet defined. The anatomical course of the sensory division of the facial nerve, between the periphery and the geniculate ganglion, has not yet been traced, but the taste fibres pass from the periphery to the geniculate ganglion through the chorda tympani and through the glosso-pharyngeal nerve. The taste fibres in the glosso-pharyngeal nerve pass, probably *viâ* Jacobson's nerve and the superficial petrosal nerves, to the geniculate ganglion.

The afferent fibres from the skin of the meatus and auricle on their way to the geniculate ganglion may travel by one or other of several routes: (1) through the auriculo-temporal branch of the fifth *viâ* the otic ganglion and the small superficial petrosal nerve; (2) through the auricular branch of the vagus to the trunk of the facial; or (3) *viâ* the auricular massage, electricity, x rays, or medicated baths, which in general practice are out of reach. Again, in respect of diagnosis, there are poor patients as well as rich whose maladies are obscure in nature or difficult to manage; patients who may have made, and be making, payments to a medical man, but are quite unable to add the fees of a consultant or the charges of costly methods of cure. Even in the poorer families of the middle classes serious illness is a grievous or even a crippling expense, especially in these days of elaborate and costly therapeutics, against which some more orderly provision is sadly needed. As things are, these important cases are more or less swamped by the horde.

How, then, is the out-patient department to be organised for efficiency, and with respect to the general practitioner, who in these latter days has become far too competent a man to be ignored? Time permits me to consider one part only of the problem. It has been proposed that access to an out-patient department shall be only by the introduction of a medical man in the district. This is too narrow a proposal. To deny a ready relief to the sick and needy who have no doctor, or know none, or in any case are unable to pay for his intervention—in cases, for instance, of incipient acute disease, of infections, or more insidious maladies—would not be, and ought not to be, tolerated by the public, whether in the name of charity or of civil order. Moreover, the delicate question must arise, How fairly the general practitioner would play the game? As things are, the ill-paid "club doctor" often, and not unnaturally, declines to add to his bounden duties; nay, the physician who resents a hint at "farther advice," or sniffs at it when obtained, is not quite extinct. Again, what about the time, the trouble, and the comparative ineffectiveness of brief notes or messages?

The proposal as it stands, then, is narrow and impracticable; yet it touches an important principle, especially as regards cases of difficult diagnosis, those again which need costly methods of cure, and afflicted persons who have paid fees but can pay no longer. To encourage family doctors to refer to the hospital patients of these two classes is then the duty of the managers; and for the cases of difficult diagnosis or treatment I suggest that the need would be met by the appointment at every hospital, and in each department, of an invariable hour when the outside physician and his patient could rely upon a consultation with one or other of the honorary staff in his respective department. These hours should be fairly frequent and invariable; the busy practitioner cannot be counting days and hours, he must be able to say offhand when John or Mary shall meet him at the hospital gates. There he would probably meet others of his brethren on similar errands; and if all could join in each consultation they would derive for themselves as much of interest and experience as of advantage for their patients. Such a system would surely extend itself in many incalculable ways; it would offer a fertile field for the younger consultants, raise the value of medical methods in the eyes of the public, and tend by example to reduce the burden of hangers-on and of routine prescribing among them, and even, perhaps, of vague discontent and quack-hankering among the well-to-do. I will only add that on the medical side provision should be made for consultation in cases of mental disease also.

MEDICINE AND THE STATE.

There is no doubt some discontent in our profession that Medicine has not the rank and consideration which are its due; such as are accorded for example to the Church, the Law, the Navy and Army. Now in so far as any such uneasiness is engendered of petty personal ambitions we need not dwell upon it longer than to recollect that we shall attain to the social consideration we may deserve by the self-respect which ignores the trivial conceits of the day, which is quick to think for others, slow of offence. But this is not all. The physician, if a somewhat touchy person, is not arrogant; the discontent lies deeper and springs from more honourable motives; from a nobler jealousy for our calling, its achievements and services; from a restless sense of great powers not finding their full play and responsibility in the national functions and counsels. Thus regarded, our discontent may be justified, and desire only what is due to the honour and interests of the commonwealth.

Now there must be some reason, if Medicine has failed hitherto to rank with the other great services, why this is so. The answer is not difficult: that in so far as we are concerned only with individual pains, in so far, as some naughty wit has put it, as we are but plumbers and glaziers of the individual body, we have neither place nor claim to public recognition. It is in respect of our concern with the larger issues of public health that our service and responsibilities become of national importance. In this respect, however, until yesterday and to-day we had not the knowledge to justify our vocation. The history of Medicine, broadly speaking, is melancholy reading; it is a record of devastation by pestilence, deplorable blights upon family life, and catalogues of medical formulas and practices as prodigious as the plagues before which priest and physician alike vaunted themselves in vain. Open the pages at hazard, perchance at John Evelyn's story, but a common instance of a common fate. Of Evelyn's nine children a son and a daughter only reached adolescence, and one of these, in the words of Jeremy Taylor, "that pretty person your strangely hopeful boy," was then cut off also; the daughter alone survived him. As in some classes even yet, in all classes then, such disaster was rather the rule than the exception, and the people went upon the facts accordingly: the fighting men, they more or less consciously argued, make us into a nation; the lawyers bring order into our midst; the Church has fostered learning and religion; it is the no less high vocation of medicine before commerce, before other subsidiary ends, to conserve and fortify man's body, the tabernacle of this prowess and this wisdom—the tabernacle, do I say? nay, in the words of Dr. Caird, St. Paul's dramatic contrast between the flesh and the spirit had but a temporary and rhetorical meaning, like the contrast between matter and energy; the body, spiritually considered, is the immediate organ and instrument of the soul. To maintain this organ and instrument not in the individual man only, but in the social body also, was the vocation of medicine, but science had hardly come to the birth and applied biology had not even been conceived. Medicine could not humbly wait for science, as science was waiting for the experimental method; competent or incompetent, she was forced to the front. Her pontiffs, therefore, strewed before the people chiefly some withered branches of tradition, and the Dead Sea fruit of a curious but mostly grotesque and unregenerate folklore. In the Middle Ages, indeed, great men could not fight for clear causes; they were confronted not only by truths in array one against another, but also by monstrous regiments of error and fiction—regiments to be mown down by the artillery of experiment, as feathered savages before the hail of the machine gun, but till then irresistible. Not till our time and with these arms victorious could medicine advance; but now it is moving so quickly that, borne on by the moving mass, we do not perceive the speed until we look back to see whence we have come. The belated knowledge is won. To-day we can answer bravely to our invocation. We are commanding the ear of the nations and solving their problems with deeds and revelations so triumphant that in their quandaries, even our unidea-ed governing classes, who had fallen to a belief in "compromise not as politics but as an excuse for routine," and had satisfied themselves of the efficacy of ignorance, are now compelled, bit by bit, to yield us some brusque and clumsy heed, to bully and then to knock under. For from the hands of our leaders the kings of the earth and its merchants have received the keys of Suez and Panama, the gates of the hemispheres; their wardens, the twin ogres of malaria and yellow fever,[1] being by our art if not dead yet toothless and impotent as Pope and Pagan; we have tortured the secret out of the demons of tuberculosis, sleeping sickness, plague, Mediterranean fever, wool-sorters' disease, cerebro-spinal meningitis, tetanus, syphilis, puerperal and surgical fevers—need I prolong the list of these modern discoveries, so brilliant as to shine best by their own light?—and where we have not yet extorted the whole secret, as from small-pox, scarlet fever, infantile diarrhœa, hydrophobia, we have so far mastered the tactics against them as to be reducing them to phantoms of their former malignity. Sadly late then as we have come into the field, we are in time to be the saviours of the nations as well as the guardians of the family; and to endow mankind with vast and fertile or even absent on occasion. The temperature was no criterion of severity; as a rule it remained moderately elevated, between 100° and 101° F.; sometimes it was scarcely higher than normal. Most of these cases had no abatement in their condition; they died during the period of acute infection, usually within the first week of illness.

---

[1] To yellow fever in Havana, year by year for some 200 years until 1902, about 750 lives were sacrificed. In the last three years not one death from this plague has been recorded there.

Others, however, whose symptoms of acute invasion were scarcely less grave terminated abruptly in recovery. The ominous signs passed off; the temperature rapidly fell and remained permanently normal; Kernig's sign and some nuchal rigidity persisted for a few days longer. This favourable crisis occurred on any day up to the tenth of illness, but the most usual days were the seventh and eighth. By the severity of their symptoms, their recovery by crisis, and their convalescence with normal temperature these cases recalled the course of acute pneumonia.

Chronic cases.—Other cases were more prolonged. Some at the outset showed an acute phase resembling that described above; others began without acute symptoms but with evidence of local infection; others, again, had a transient acute invasion. Surviving the early days of their illness and entering a chronic phase, they tended to end by a lysis with considerable morning remissions. The duration of these cases varied within wide limits. Frequently, however, the temperature became normal within four weeks or thereby from the onset, so that recovery by lysis in four weeks' time came to be regarded by us as a common favourable termination for cases that survived the acute period. We ascertained by examination of the lumbar fluid that resolution was proceeding side by side with the decline in temperature.

During the continuance of the disease in its chronic form the condition of patients fluctuated in an uncertain manner from day to day. Sometimes they remained free from symptoms for a complete day or even for a few days, and thereupon entered on a period of headache, restlessness, irritability, and pyrexia. Sickness, too, was apt to recur from time to time between quiescent intervals. Such successive remissions and exacerbations were distinctive features of the chronic group.

From what has been said above it will be sufficiently apparent that spontaneous improvement in the condition of patients was liable to occur during the natural course of the disease as seen by us, alike in the acute group of cases with their critical recoveries, and in the chronic group with their oscillations between betterment and relapse. After serum treatment during the acute phase in certain of our examples the temperature suddenly fell and the symptoms passed, but this early favourable termination, as noted above, was by no means uncommon in our untreated patients. The clinical appearances after serum treatment in the chronic phase were not less equivocal. In some cases decrease of restlessness, headache, and general irritability occurred on the day following administration; in other cases two days later. In some cases the improvement was lasting; in others the symptoms recurred. Some cases again which had several injections of serum reacted differently with the different injections; a particular dose might appear to produce a satisfactory abatement of symptoms and a second dose for recurrence seem quite inert. Relapses were not prevented by serum treatment either during the acute or chronic phases of illness. In their influence on the phenomena of the disease frequent injections and large injections did not differ from injections at longer intervals or in smaller quantity.

On these observations we base the view that the administration of serum to our cases was followed in individuals by no consistent modification of the natural course of the disease.

STATISTICAL CONSIDERATIONS.

In the absence of clinical indications that benefit was derived from the serum we turn to the statistical side of the question. We compare treated and untreated cases in respect of case mortality, duration of fatal illnesses, duration of illnesses ending in recovery, and survival beyond the first ten days of illness. With reference to the course of the disease we have recognised two periods of time; one is the first ten days—days 0 to 9 of the tables; the other begins at the close of day 9. During the first ten days our cases, almost without exception, concluded the acute phase of their illness either by death, recovery, or passage to the chronic phase. Those which ended by death or recovery form the acute group of the clinical section. During the second period our cases were in the chronic phase; these are the chronic group of the clinical section. We have recognised the same two periods in considering the date on which serum treatment was begun with the view of noting the effect of early administration.

Case Mortality.

Total.—Of the 330 cases 83 recovered, while 247 died, a mortality of 74·8 per cent. for the total cases apart from the question of treatment. This figure is nearly approached by a mortality of 74·7 per cent. among 83 cases at Leith reported by Robertson (1907). Billings (1906) records 2755 cases in Greater New York, of whom 73·5 per cent. died; and Ames (1908) speaks of 166 cases in Boston City Hospital which had a mortality of 72 per cent. At Königshutte, according to Curtius (1905), among 200 cases 70 per cent. lost their lives; and 230 cases at Belfast, as noted by Robb (1907), had 70·43 per cent. of deaths. Other recent statements are appreciably lower. In the administrative district of Oppeln, as detailed by Kirchner (1905), over the period 1895–97, of 297 cases 41·4 per cent. proved fatal, while in the same area in 1905 during the Silesian epidemic the case mortality of 1955 sick persons was 51·2 per cent. 45 cases at Milan in the spring of 1907, as indicated by Bordoni-Uffreduzzi (1907), lost about 27 per cent. of their number; and in a military report published at Berlin (Genickstarre Epidemie, 1905) there is an account of an outbreak which attacked 26 men in a battalion, with a case mortality of only 3·8 per cent. Our cases had thus a higher total mortality than any of the records cited.

Serum treatment without reference to period of administration (Table I.).—Of the 330 cases 105 were serum-treated and 225 were not so treated. Among the 105 serum-treated cases, with 68 deaths, the case mortality was 64·8 per cent. Among the 225 untreated cases, with 179 deaths, the case mortality was 79·5 per cent. Considered with reference to the number of cases involved and also with reference to the fact that many cases admitted *in extremis* during the acute phase of the illness did not receive serum treatment, the difference between these percentages is barely significant. Our mortality of 64·8 per cent. for treated cases may be compared with other records. Robb (1907) with various sera treated 79 cases, of whom 74 per cent. died. Raczynski (1907), using Jochmann's serum, with nine cases had 66 per cent. of deaths. Krohne (1908) reports a fatality-rate of 47·6 per cent. among 135 patients, in the administrative district of Düsseldorf, who were treated with various sera, and Wassermann (1907), for 57 treated persons, states a case mortality of 47·3 per cent. Jochmann (1906) records 17 serum-treated cases with 29 per cent. of deaths at the time of his writing, and Flexner and Jobling (1908), among 47 cases which had their serum, report 27·6 per cent. mortality. Robb (1908), treating 30 patients with Flexner and Jobling's serum, had a mortality of 26·6 per cent. Dunn (1908), giving Flexner's serum to 15 cases, lost, or expected to lose, about 20 per cent. of their number. Lastly, Levy at Essen, with Kolle-Wassermann serum, had 11·76 per cent. of deaths among 40 sick. By these standards our treated cases had a somewhat high mortality.

Serum treatment with reference to period of administration (Table II.).—For the 105 serum-treated cases Table II. shows the day of illness on which serum treatment was begun. One case which proved fatal had serum on day 0—that is to say, within 24 hours of onset. Among 15 cases in which serum treatment began on day 1, with 13 deaths, the case mortality was 86·6 per cent. On day 2 the mortality was little less than on day 1, while from day 3 to day 7 inclusive the percentage of deaths was appreciably lower, varying from 30 to 66·6 per cent. After day 7 the number of cases on single days or groups of days was in general less than on the earlier days; but the eight cases opposite day 15, with three deaths, had a case mortality of 37·5 per cent.

It will thus be observed that the mortality was highest among the cases in which serum treatment was begun during the early days of illness. This disposition of case mortality is at variance with the results of serum treatment recorded by Wassermann (1907), who found that among 57 serum-treated cases regarding which information was obtained, the mortality rose from 21 per cent. for the first to second day of illness and 28 per cent. for the third, to 75 per cent. for the sixth day of illness and 80 per cent. for the fourteenth day. We do not ascribe this difference of case mortality to of all irresistible knowledge; and a proneness to the sinister device of "*Divide et impera.*" Moreover, the English public has a wholesome dislike to the multiplication of officials; but by organisation the number of officials at any moment would be diminished rather than multiplied. *It is true that* each department would still need its own standing medical counsel as it has its standing legal counsel; but how far more valuable would such a counsellor be when speaking from the consolidated opinion of a *corporate and disciplined* medical Ministry than as an isolated medical *colleague* expressing no more than individual opinions. The crying need of reform in the separate peripheral areas must be freely admitted; and Dr. Bushnell[3] *is correct in attributing to me an* "*apprehension* of harm in excessive or premature centralisation, lest *the* central machinery be too powerful for the peripheral equipment." But, on the other hand, without parallel development, coördination, and distinction of central powers, how are local authorities and local medical officers, in all the far-reaching and various departments of national function now *being intrusted* to them, to derive their instructions and judgment, to command attention, to be supported in their legitimate functions, to be furnished with knowledge, and to be inspired with earnestness and devotion to duty?

CLINICAL PROFESSORS.

In passing now from hospital and public medicine to the school, I would congratulate this University on the recent appointment of responsible professors of medicine. The rich services and the accomplished staffs of the London hospitals fall far short of their potential capacity because in this respect everybody's business is nobody's business. By general report, by the uneven quality of the clinical training of Cambridge students in London, and by personal comparison of the services in great continental hospitals, or, indeed, of Edinburgh Infirmary as it was in the days of Begbie and Stewart when I knew it best, and as no doubt it is still to-day, I note in foundations so magnificent as the half dozen chief London hospitals that their defect of responsible clinical professors results in grave shortcomings. The apprenticeship system died out and no other methodical system took its place. Admirable are the gifts, devoted are the sacrifices of individual physicians and surgeons, and by such virtues this member of the staff or that gathers for a time a fairly regular class about him; yet he is but an unpaid or ill-paid volunteer, whose personal and private interests must be his chief consideration. None of the senior staff is invested with specific duties or responsibilities. *Thus as a whole the teaching is* without system, without concentration, without definite standards. At the best it is a procession of brilliant episodes; in the mean it is casual drills under no commanding officer. Where in these great hospitals do we find, as in France and Germany, a clinical professor of experience no less ripe, of repute no less eminent, devoting the best of his golden hours to the hospital; making and controlling his *assistants*, and guiding his classes in research, working out leisurely his own problems before their eyes? In our visits to great English hospitals do we not see more frequently the great physician or surgeon flitting rapidly from bed to bed, hemmed in by a crowd of foreign admirers, dropping indeed as he goes pearls of wisdom, but educating nobody? *His seed thoughts* we pick up thankfully, but still we want also the curious, the leisurely, responsible professional teacher, such professors as you fortunately now possess in those eminent physicians Dr. *Graham Steell* and *Dr. George* R. Murray.

MEDICAL STUDIES.

Although in my little book on "Professional Education"[4] I have dwelt at some length on medical studies, yet the present occasion and the recent discussion at Sheffield seem to call for some reiteration of opinions for which hitherto I have obtained more attention outside our profession than within it. I hope it is a pardonable conceit on my part to surmise that, had they been noted at Sheffield, the discussion would have moved toward clearer issues and led to more definite conclusions. To-day I can but touch upon the central problem, the evasion of which at Sheffield gave an arbitrary character to what might have been a very important debate—namely, *the relation of university to technical study.* When *directly* challenged, all competent observers admit that education does partake of these several qualities; and that however commingled in practice, however conflicting, the virtue and functions of each must be discriminated, valued, and compared. Moreover, it is generally admitted that as *university education,* looking as it does to the man and to the future, is apt to be thrust aside for technical equipment which is for immediate gain, the cause of individual development and future knowledge should be the more jealously guarded. Forgive me if under limits of time I put the matter bluntly. A father says, "I can spare neither the time nor the money to give my son a university education, in the proper sense; indeed, I am not sure that I *desire it*; I do desire to make a special workman of him, and as soon as possible; all beyond this may bring in no more than its own reward. Yet, as many universities have been granting medical degrees on diploma standards, and for training no more than technical, these degrees have become an indispensable business asset; consequently my son must have the stamp, not as a mark of a liberal education, about which I am *not now concerning* myself, but to testify to good average technical attainments. Specifically I *mean that every candidate, competently* instructed in the art and mystery of medicine, must be furnished with an M.D. degree." This is the idea now prevailing in our profession and the claim is a serious one; perhaps, in the tangle of these matters, irresistible. At any rate, as things are, it has my sincere sympathy.

There is, however, no inconsiderable part of our profession which goes not quite so far. This party, while still regarding the curriculum as narrowly from the technical point of view, *would*, however, hold back the university degree *for a* minority of candidates who have distended their minds with a bigger content; though still of technical stuff. With this party I have less sympathy, little or none. If for mere technical instruction the world compels us to give the seal of a university—that seal which ought to attest a disinterested education, aiming chiefly at the making of the man himself—well, we have the recognised excuse of duress. For in the past technical medicine has edged its way into the machinery of the universities as no other technical instruction has done. Save in this anomalous case of medicine, universities have never regarded themselves as engines for the manufacture of professional men as such. The parson is made in the seminary and the parish, the lawyer in chambers and court, the soldier in the field, the engineer in the workshop, and so on. To none of these does the university give the seal of practical competency; it testifies to the individual development only. By this anomaly in medicine our conception of a liberal education has been so warped, or at any rate so confused, that university degrees on diploma standards may be inevitable. But, I repeat, I can feel no *sympathy with the party* which, by withholding the degree until as much of this erroneous conception as possible may be accumulated, would give our principles away more completely and force the universities to the manufacture of pedants. For the more intense the specialism the deeper and broader must be the universal foundation. The function of the university is to make the man; and if the man be but half made—I am speaking, of course, of the average student, not of the genius who makes himself—the greater burden upon his back serves only to exhibit the slightness of his frame. A technical instruction cannot by mere length and toughness become a liberal education; yet herein the Sheffield discussion reminded me of the old comparison between rheumatism and gout: turn the thumbscrew till the pain is intolerable and you have rheumatism; give it another turn or two and you have gout. So with study: by turning the screw beyond the already exacting pressure of the medical schools we are to carry the technical into a university education. Wince from the truth as we may, a liberal or university education is primarily of different scope, and means a different method and course, not at the end of the curriculum but from the beginning; the professional school, however exacting, educates the average physician not otherwise than the clerical seminary educates the average clergyman.

But, it may be urged, if we can entrust a university with our technical training, and can set a hospital in the middle of it, shall we not get the best of both worlds? Will not universal methods and scholarly standards mould the technical methods on lines which, if not as generous as could be wished, may yet be fairly ample? Can

[3] Brit. Med. Jour., August 29th, 1908.

[4] Published by Messrs. Macmillan, 1906.

11 cases, or 23·9 per cent., and days 10 upwards in 35 cases, or 76·1 per cent. According to Table XI. the administration of serum did not appear to increase the number of recoveries during the acute phase of the illness.

Date of permanent return of temperature to normal with reference to period of [illegible]*um (Table XII.)*—In this table the [illegible] whose treatment began during days 0–9 [illegible] untreated cases. The conclusion is the same as in Table XI.

Survival of Days 0–9.

Number of cases surviving days 0–9 (Table XIII.).—It remains to ascertain whether it is possible that serum treatment within the first 10 days of illness—apart from the question of ultimate death or recovery—had been instrumental in inducing the survival of treated cases beyond the period in question. In Table XIII. the survivals of patients whose treatment began during days 0–9 are compared with those of untreated patients. Of 89 such serum-treated cases 54, or 60·7 per cent., survived the 0–9 period. Of 225 untreated cases 133, or 59·1 per cent., survived the 0–9 period. The percentages are all but identical, and no influence of serum treatment can be discerned.

Mortality of cases surviving days 0–9 (Table XIV.).—When, however, the mortality among serum-treated cases which survived days 0–9 is contrasted with that of untreated cases which survived the same period a difference is readily noted. Among 54 serum-treated cases which survived days 0–9, with 25 deaths, the mortality was 46·3 per cent.; while among 133 untreated cases which survived days 0–9, with 87 deaths, the mortality was 65·4 per cent. The proportion differs by almost 20 per cent. in favour of serum-treated cases. From this point of view, therefore, serum treatment within the first 10 days of illness seems to have had a limited good influence. Though serum-treated cases did not survive days 0–9 in greater number than untreated cases, yet serum-treated cases which did survive ultimately recovered in greater number than cases not treated with serum. The effect of serum would appear to have been to improve the prospect of recovery of cases which survived the first ten days of illness.

CONCLUSION.

An examination of our cases of cerebro-spinal fever during the period covered by this report, while leading in general to a negative conclusion, has nevertheless revealed one result in favour of serum treatment. It is true that on the clinical side we have not seen any obvious or constant train of events following the injection of serum; and on the statistical side we are unable to report that total case mortality was reduced, or fatal issues delayed, or favourable illnesses curtailed, or even that after administration of serum there was an increase in the number of patients who survived the first 10 days. But when, as in Table XIV., serum-treated survivors of the first 10 days are compared with untreated survivors in respect of case mortality, it is found that the treated cases recovered in greater number, and the difference between the respective percentages is sufficient to carry the implications that serum-treated cases which survived the first 10 days of illness had a better chance of life. This result, as we think, is significant; it suggests that the treatment in these cases, though failing to arrest the disease out of hand, was yet able to hamper its progress, aiding in this way the natural defences of the body and hindering in all likelihood the formation of exudates which would stand in the way of recovery.

We have already stated that the relatively high general fatality among our serum-treated cases and the absence of demonstrable benefit from early administration are to be ascribed, at least in some measure, to the severity of the acute phase during the time when the disease was most prevalent in Glasgow. But the part played by the site of injection and by the quality of the sera used may also be borne in mind.

As regards the site of injection our cases, with exceptions, had serum at least on one occasion into the spinal theca, after the withdrawal of cerebro-spinal fluid. Our frequently repeated injections, however, were subcutaneous for the most part, and our massive injections were necessarily so. Our results do not favour the combined method. More successful records have been obtained by others with exclusively thecal injections. On general grounds the thecal site seems better suited than the subcutaneous for the application of a bactericidal remedy to a local bacterial infection; and it is of interest to note in this connexion that McKenzie and Martin have shown that the cerebro-spinal fluid of cerebro-spinal fever cases did not contain substances which were bactericidal to the meningococcus *in vitro*, even when the blood serum of the same patients had markedly bactericidal properties.

As regards the quality of the sera used, it may be that the most recent sera have a higher specific value than those accessible to us during the period under notice. One of these recent sera, that of Flexner, is now in use here. The results of its administration are not embodied in this report. They will be recorded in due course.

We may conclude these remarks with a comment on early administration of serum as applied in acute and chronic cases respectively.

It is stated by authors that early administration is the essential condition of success in serum treatment, yet it is evident by Table II. that our earliest treated cases had the highest mortality. These acute cases, however, proving fatal shortly after admission and coming to section, were found to show general meningitis, hæmorrhagic patches, copious exudation, and the like. Their disease had run a rapid and virulent course. They were admitted, one within 24 hours, some within 48, and some within 72 hours from onset, but their chances of recovery, as the issue proved, were already compromised. With attacks which may be beyond control in a few hours from the first appearance of symptoms timely serum treatment is difficult to attain. These cases, though early within reach of treatment, were presumably not early enough.

Chronic cases, on the other hand, which survived the acute toxæmia became the subjects of profound pathological changes. Hydrocephalus, for example, led to death in our experience long after the stage of acute infection and after a study of the cerebro-spinal fluid had shown that the greater part of the exudate had disappeared. Post-mortem examination disclosed either complete resolution of exudate or organised exudate at the base of the brain. In such cases

thing is smaller than another, to the small mind everything is insignificant. Herein the American surpasses the English plutocrat; he sees beyond the counter, he has faith in the best knowledge in every field; we have not this salvation. Let me contrast with such complacency the words of an even more considerable teacher: "You are citizens of the great and mighty city of Athens (a city by the way mightier than any of ours); are you not ashamed of heaping up the greatest amount of money and honour and reputation, and caring so little about wisdom and truth, and the greatest improvement of the soul which you never regard or heed at all?" German commerce is teaching us the bitter lesson that even in his own material field your "practical man" over-reaches himself; that his "good workman" is unable to investigate even practical problems, to appreciate the discoveries of others, or to teach his apprentices. If he is to transform human energies into the best material results the practical man must have the best kinds of minds at his service; not merely the handy man, sharp and resourceful in common emergencies, but of no insight and no horizons.

PORTAL OF QUALIFICATION.

If then a university degree is to be exacted for utilitarian teaching which, as it is to occupy only the time officially prescribed for a diploma, cannot attain to university standards, we shall lose sight of the first principles of all education and barter away the foundation of medicine herself and of all progressive knowledge. It has been, however, as I have said, a part of the anomaly of university medicine that for this profession universities have been endowed, or shall I say "saddled," with the duty and responsibility of qualification for practice; a concern which, as we have seen, is none of theirs, or is theirs only in common with society at large. By the establishment of one portal to the Register the State will, I trust, soon relieve us of this alien burden and of the duty of tests no less alien to our best purposes. At Cambridge, indeed, I consider that to impose upon those of our M.B.-B.C. candidates who are already on the Register, as are some 75 per cent. of them, a repetition of these diploma tests, is not only otiose but a grave evil; it prolongs what Professor Starling well calls the "stuffing" period, the period during which the candidate denies himself the wards that he may sit in his lodgings with a teapot, and a wet towel about his brow, fagging up handbooks. The contents of these, in dilute solutions or on sheets divided into opposite columns of neatly docketed cram, he retails to us over again at Cambridge. Now many of these candidates, as later we find by their M.B. theses, we really had led to think for themselves; yet in a qualifying examination they dared not venture to betray it. Occasionally an audacious spirit may enter a timid demur to current doctrine or phrase, and if so, from me at any rate, he obtains a good mark, whether his demur be justifiable or not. But, if I exclude the few riper students who give more time to the university, I can hardly recollect a paper in medicine in which a candidate broke away from conventional notions and sheepish assent. Man by man and year by year, their papers are as conventional and as flat as willow-pattern plates.

TESTS OF METHODS.

But it may be urged, are not these remonstrances rather fanciful, rather academic, counsels too rare for a common world! Well, we will try, as the children say, to prove our sum. We must go beyond these tests of current doctrine and common formulas, of the capacity of swallow and regurgitation by which our examination candidates regularly amaze us. We shall seek a test not of the volume but of the design of the candidate's work, of the power and quality of the human organ we profess to have built; of the personal character informing his notions. We shall mark whether his argument signifies that his ideas were spun in his own loom, or are all warehouse goods; and if in the accuracy and lucidity of his language he betrays a precision and balance of thought. We shall note as highly significant such fresh observations and ideas as offer themselves on all sides to the developed intelligence, the quickened eye, and the arm which has learned to know the quarry and handle the pick.

Whether the qualities of the university graduate are as remarkable as they should be in current medical writing it might be ungracious at present to inquire; and I must not assume the truth of the recent complaints that English Bachelors of Science, when they visit Germany, are found to be trained so much on books and laboratory clerking, and so little on personal initiative, that their education has to be recommenced on better lines; I must then confine myself to one, but this a definite, test. At Cambridge, before an M.B. candidate can receive his degree, he must prove to us that, however well "stuffed" a pupil, he is able also to show that he is not a mere mouthpiece, but in some reasonable measure has developed and realised his own personality. Before he is admitted to graduation he must show us not only how much he can repeat, but hidden under the pile of his tasks and cram he must also discover himself. Plaintively as at first he may protest that he has nothing "original" about him, he has none the less to set to work on some piece of research—when to his surprise and pleasure he usually finds out that we had made a thinking and even a creative being of him after all, and on this discovery he goes into practice a different man. But this research work for the M.B. is unfortunately the boon only of Cambridge men. I have therefore to seek my test in the M.D. exercises, where, if at all, lies the test of personal construction as contrasted with borrowed furniture. The M.D. candidate is too old for examination and he should be too good for a test so coarse. Therefore, every university, perhaps all universities, began by making the M.D. dissertation the chief test of its peculiar influence, of its formative discipline, of its power of developing the mind as compared with mere schooling. Yet what are we witnessing to-day? That even this one test, the one test of the quality of the university itself, as well as of its progeny, is being quietly evaded. On inquiry I find that now of the M.D.'s of the London University scarcely more than 10 per cent. give evidence of this or any such developed and ripened faculty; and it is whispered to me that on this same path even Victoria is a backslider. Yet is not this not only to relinquish all interest in the higher qualities of our students, but also tacitly to shrink from the wholesome test whether a university has justified itself as such, or, under whatever duress, is allowing itself to be dragged down to the place of a mere technical school? This can but mean stationary pupils, and stationary pupils make stationary teachers; if a university is to become an organ of life and discovery it must begin and end by making research compulsory all round. Research must as surely be implied in the earliest stages of the teaching, as actively developed and testified in the later.

REASON, IMAGINATION, AND LIFE.

And now, in conclusion, may I turn myself for a moment to the young men entering into or crossing the threshold of medicine. You have heard me insisting upon the power of knowledge, you have heard me resenting that worst part of ignorance, the conceit of knowing what we do not know, and the inveterate habit of calling opinions "facts"; you have heard me lamenting the English fatuity of disregarding causes to throw all our energies into mopping up their consequences; and you may begin to accuse me of the creed of the Jew of Malta, "I count religion but a childish toy, and hold there is no sin but ignorance." Far indeed from me be any such counsel! I agree that a man's overbeliefs are the most interesting thing about him. I bear in mind Carlyle's judgment on one who "had a great deal of unwise intellect." I see that the lower the idea the easier it is to formulate it; so that in our satisfaction with the solidity of our foundations we are prone to forget the superstructure for which ethical and imaginative insight must also be enlarged and illuminated. For if in logic we distinguish these endowments, if indeed in practice some may be nursed to the starvation of others, yet in the fulness of life they make each other, interpenetrate each other, and are bonded together. If then, limited by our prejudices or wearied by the quarrels of sects, we divide them in the mimic life of education, if we constrain our schools and universities to force intellect to the impoverishment of ethical and imaginative faculties, or even to nurse them in separate compartments, evil rather than good will ensue.

> "My brain I'll prove the female to my soul,
> My soul the father."

In the everyday world we observe, even in persons of moderate parts, that character, consisting in a high idea of duty, in an intuitive perception of the essential and a sense of relative values, a generous sympathy with various human

Glasgow.

AN ATTEMPT TO REHABILITATE THE PERMANGANATES.

BY E. C. BOUSFIELD, D.P.H. CANTAB. & LOND.,

DIRECTOR, CAMBERWELL RESEARCH LABORATORIES, AND BACTERIOLOGIST FOR THE METROPOLITAN BOROUGHS OF CAMBERWELL AND HACKNEY, ETC.

MORE than half a century has passed and a whole scientific world has been opened since the action of the permanganates as disinfectants was first brought to the notice of the medical profession. Indeed, this first of popular disinfectants was, in the time of its introduction to public notice, coeval with the first actual observation of a bacterium, that of anthrax, by Pollender in 1855. With the growth of bacteriological science and the recognition of one concrete agent of infection after another, numberless other claimants to destructive powers in connexion with them have been more or less successfully exploited, and except for popular use and upon vague and indefinite lines the permanganates as disinfectants have almost dropped out.

It is the purpose of this article to inquire how far this neglect is justified. The permanganates have many qualities which, given a reasonable disinfectant power, entitle them to consideration. Their very great power as generators of nascent oxygen, their non-poisonous character, their cheapness, and, lastly, their distinctive colour, are all features of value, whilst they alone possess the power of destroying the odour of putrescent matter and of thus affording, in the absence of odour, a very evident, if somewhat rough-and-ready, criterion of the amount of disinfection which has been effected. Finally, they have the advantage of leaving the substance to which they have been applied, whether solid or liquid, in a condition in which it is incapable of giving rise to disease either by the bacteria contained in it or by their products.

Having been consulted with reference to the choice of a disinfectant for a system of sewage disposal, which should be cheap, non-poisonous to both plants and animals as regards the subsequent disposal of the sewage, and yet should sterilise the sewage for the time being, the writer's choice was necessarily greatly narrowed down, and the only substances available appeared to be the cresol compounds and the permanganates. It was essential that the matter should be soluble, since a part of the system consisted in the addition to the sewage in its flow of a carefully and automatically measured amount of the substance chosen. The choice finally narrowed itself down to permanganate of potassium, izal, and Jeyes' fluid. The two latter had been more or less closely investigated, but it soon appeared that of the first named nothing exact was known at all. It was therefore necessary to institute a series of comparative experiments, keeping in mind the question of cost in large-scale working, and in the circumstances it was obvious that no method of testing, other than that carried out on the lines of actual working, could possibly give useful results.

The experiments were accordingly carried out as follows. Crude sewage actually flowing in the sewers of Camberwell was drawn up in a bucket, divided mechanically as completely as possible, and then placed in quantities of 10 cubic centimetres in a series of tubes. To each of these tubes except the first was then added 1 cubic centimetre of a disinfectant to be tested, the solutions being made 11 times as strong as the dilution to be tested, so that the latter might be present in the tube in the proper proportion. The first tube was at once diluted 100,000 times in a series of flasks of sterile tap water, and cultures were made to the number of three, each with 1 cubic centimetre of the dilution, in alkaline nutrient gelatin. These were incubated at room temperature, and furnished a standard of the number of bacteria present in the sewage. The disinfectants used were as follows:—

Permanganate of potash Jeyes' fluid ... ... Izal	1–5000: 1–2500. 1–1000.

These were allowed to act upon the sewage in the tubes, finally the practitioner into whose daily routine its influence has crept and whose future it will certainly mould." Dr. Slater proceeded to give an account of the evolution of laboratory training and equipment which has taken place in St. George's Hospital of recent years. This led him to a consideration of the causes which induced its medical school to give up the teaching of the "preliminary and intermediate" subjects of the medical curriculum, a decision to which he felt sure other London schools would be driven sooner or later. In support of this contention he gave a very able and comprehensive summary of the present unfortunate position of medical education in London, of the severe competition for students of provincial universities, and of the unfortunate disagreements which have led to the handing back by the University of London of £70,000 to the would-be founders of a Central Institute of Medical Sciences. He deprecated the rapid increase in licensing bodies and advocated strongly the introduction of a "one-portal" system of qualification, and the bestowal of degrees by the Universities only upon State-qualified men. We regret not having space to report at length this part of Dr. Slater's address, but as the arguments which he used are known to most of our readers we have chosen the second part which dealt more especially with the scientific education of the medical student and the relationship of the laboratory to clinical medicine. After pointing out the advantages of a "one-portal" system, he proceeded:—

In addition to the modifications in medical education which either have been, or will be in the near future, forced upon us by financial difficulties due to the growth of science we have—and this is the factor of greatest importance to the student—the effect produced by the time taken by the scientific subjects which either lengthens the curriculum or robs the professional subjects of their due proportion of time. Probably none of the subjects introduced into the syllabus of medical studies, even that of the University of London, are, considered in the abstract,. undesirable, but it is also desirable that the student should be able to get qualified before he is grey-headed. The time taken before a medical man is in a position to earn his living is already very long and cannot be lengthened without harm to the profession. It is not surprising, therefore, that at the present time the educational pruner is anxiously looking to see what branches may be cut back from the tree of scientific knowledge, both to render it more fruitful in itself and prevent it from crushing out other branches of learning which suffer from its overshadowing. Attempts have been made to meet the difficulty by ordaining that only so much and no more of the curriculum shall be spent on the preliminary and intermediate subjects. But this is a paper regulation—a Partington policy—you cannot stop the Atlantic of science with the mop of a syllabus. The minimum time before which a student may not go in for an examination may be fixed but if no reduction is made in the amount which has to be learned there is but little use in reducing the time in which the student is permitted to learn it. Whether the necessary alteration in the teaching and equally requisite alteration in the examination which would be required to make these regulations effective will be introduced seems in the light of the discussion at the British Medical Association somewhat doubtful. The methods advocated by the various speakers for shortening the time required always, when stripped of phrases, took the form of a cutting down the instruction in subjects other than that taught by the speaker. It is instructive to note that the practical result of the alteration of the University of London syllabus designed for this express purpose is to lengthen the curriculum by six months. It is said that as the examiners are generally medical men there would be no danger of examinations taking a form inimical to medicine. Experience shows that this is not the case, and it is especially in the scientific subjects of the curriculum, where the connexion between the teacher or examiner and medicine has never been close and tends more and more to widen, that the risk becomes most serious. The most important suggestions made in the discussion related to the teaching of science in the schools and to the teaching of the intermediate subjects not as pure sciences but as applied science—science in relation to medicine. All practical exercises and theoretical instructions were to be such as would be of service to the student in his profession. Possibly this could be done, though there would be grave risk of our giving that half-knowledge which is so great a danger in most systems of technical education and which is so useless if progress is to be made. Still there is no doubt room for economy of time in this direction. With regard to the elementary subjects chemistry and physics, these are well fitted for the educational purposes of the school; in them a standard might be reached which with some mechanism for the granting of school certificates such as those which free the undergraduate from his "Little-go" might enable the medical student to start his intermediate subjects at once.

With regard to the scientific teaching of the student in his later stages after the intermediate subjects have been disposed of there is less difficulty. The laboratory and the wards should go hand-in-hand. It is much easier to make the problems furnished by the ward subserve the purpose of the teacher of pathology and bacteriology; in fact, the problems of the ward are also those of the laboratory, the difference lies merely in the side from which they are attacked. If the exigencies of examinations would allow, and one of the latest changes in the Cambridge examination was designed for this end, the ideal course would be for the student to take a short practical and theoretical training in pathology and bacteriology—clinical pathology as it is sometimes called—fitting him to take advantage of his clinical instruction and enabling him to examine his cases by the simpler laboratory methods. During his later years after he has spent some time in the wards and acquired some clinical knowledge and has learnt what are the problems of the bedside, he should then return to a fuller course of pathology and a further practice based on ward work of the methods which are used in the solution of these problems. As a matter of fact, that is the way things have worked out here, though to a certain extent accidentally, and I think with satisfactory results. Professor W. Osler's contribution to the discussion to which I have already referred was concerned almost entirely with this stage of the student's education, and his recommendations are valuable though they quite ignore considerations both of time and expense. Among other desiderata he suggests well-equipped rooms in which men fresh from the laboratories of the school may be trained in the use of instruments of precision in practical medicine, and a good clinical laboratory attached to the hospital in which each senior student has his place and apparatus. As I have hinted, he also includes numerous and well-paid teachers and ample time. There is no doubt that the establishment of clinical laboratories—i.e., pathological laboratories used for the purposes of diagnosis and research—has much facilitated this side of the educational problem and has been the lifeboat which has saved the schools from financial storms which would have arisen in the strictly professional practical courses as they had done in the preliminary and intermediate subjects. It was possible quite legitimately to economise by utilising for the purposes of advanced study the resources of the clinical laboratories which the progress of medicine has compelled the hospitals to found and maintain. It was an economy in salaries and maintenance to both the hospital and medical school and the work carried on in such a laboratory is obviously of the highest educational value to the properly trained and equipped senior student or post-graduate worker. If such a laboratory is not utilised so fully as might be desired perhaps this is due to lack of money and time—time of the staff and of the student. There was a period when this happy solution of a difficult problem seemed in danger owing to the ill-advised action of a commission of the King's Hospital Fund, but the common sense of the public brushed aside difficulties raised as to the use of hospital funds for school purposes when it was shown that the hospitals gained by the arrangement and that to veto this action would have been very bad economy. With us at St. George's the necessary hospital service has been provided by organising the pathological, chemical, and bacteriological laboratories with their staffs, together with the curator's department into a clinical department with arrangements for recording and correlating the work of the individual laboratories and for linking these by means of the registrars with the wards. It is in keeping touch with the clinician—in what might be styled the intelligence department—that the chief difficulties are met with in combining what tend to be isolated observations so as to subserve the purposes of true scientific advance.

The rise of preventive pathology and its development into preventive medicine during the past 30 years has naturally

M. Balthazard of Paris. The various bacterial infections are first described and the account of each is prefaced with a detailed description of the pathogenic organism, its growth, its method of action, and its effects in animals. The diseased conditions produced in man are carefully detailed, including the complications, the varieties, and the modes of infection. Diagnosis and treatment are then considered. The general arrangement is excellent and the accounts given of each disease are full and interesting; that devoted to enteric fever may be specially mentioned as constituting almost a monograph on the subject, since although no references are given the names of authorities are quoted for most of the statements made. Sections devoted to maladies produced by agents as yet undetermined, by fungi, by protozoa, and by large parasites follow. The description given of syphilis is also worthy of special notice. The account given of the treponema pallidum and its relation to the disease is most interesting, as might have been expected from M. Nicolas who has been active in establishing its importance in regard to the disease. In dealing with the intoxications, M. Balthazard discusses the rôle of the various forms of intoxication in pathology and then describes the mode of action of poisons and the defensive mechanisms of the body. The toxic effects of arsenic, phosphorus, mercury, and lead are considered in detail and the appropriate treatment is indicated. Certain organic poisons are next dealt with, including opium, alcohol, tobacco, and food intoxications. Among the auto-intoxications, myxœdema, exophthalmic goitre, tetany, sclerodermia, and acromegaly are included.

In the second volume M. Balthazard describes the diseases of nutrition and those of the blood and blood-forming organs. Among the diseases of nutrition, the account given of diabetes is worthy of special notice, that on gout being less exhaustive. In the section on diseases of the blood stress is laid upon the view that chlorosis is the result of a defect in the development of the cardio-vascular system and of the genital organs, as was originally maintained by Rokitansky and Virchow, a view which finds but few adherents in this country. A good account is given of the various forms of leucocytosis, both normal and pathological, and the forms of leukæmia are carefully described. Diseases of the heart and lungs are concisely but thoroughly described by M. Macaigne, the subject matter being well arranged. The forms of pulmonary tuberculosis are described at some length. The appropriate treatment of each condition is fully detailed.

The third volume contains articles on the diseases of the digestive tube, the peritoneum, and the pancreas, by M. Balthazard, and stress is laid on the importance of early diagnosis in cancer of the stomach and in conditions of perforation of the stomach and intestine. M. Claude contributes the section devoted to the liver, kidneys, and suprarenal capsules, and the subject matter is well up to date. The considerations of the methods of estimating the renal function and that of the subject of uræmia are both worthy of special commendation. The account of the various forms of cirrhosis of the liver is clear and interesting, as might be expected from the French school, to whom we are indebted for much information in regard to these conditions.

The fourth volume is devoted entirely to diseases of the nervous system and is written by M. Cestan of Toulouse and M. Verger of Bordeaux. The diseases are considered under various groupings and special attention is devoted to the symptoms in regard to locality and then each disease is separately considered. The various inflammatory affections of the nervous system also receive special attention and the concluding section is devoted to the neuroses. This volume constitutes an excellent manual of diseases of the nervous system and is well illustrated by figures and plates.

French text-books of medicine are usually well written and conveniently arranged. We can strongly recommend the present work as an admirable summary of the present knowledge in regard to medical diseases. Although references are not as a rule given the names of authorities are generally quoted, and the authors have not confined themselves to French workers but quote liberally from English and German writers. One of the most commendable features is the importance which is accorded to pathological considerations and their clinical applications.

Cast Iron House Drainage, with Especial Reference to the Drainage of Town Houses. By GERARD J. G. JENSEN, C.E. London: The Sanitary Publishing Company. 1908. Pp. 206. Price 4*s.* 6*d.* net. Also by the same author and another (name not given), *By-laws as to House Drainage and Sanitary Fittings made by the London County Council, with Annotations.* Second edition. Same Publishers. 1908. Pp. 147. Price 3*s.* 6*d.* net.

THE first of the above works is intended to emphasise the importance of using iron drains in town houses, especially when they are laid under a house. In these days of heavy motor traffic and of tube railways the necessity for their employment has been pretty generally recognised. Indeed, 20 or even 25 years ago iron drains found favour with the more advanced sanitarians. The book will be found a useful guide to that large class who intend to adopt the system but have not yet done so. It combines the advantages of a well-illustrated catalogue with valuable and independent criticism as to the desirability or otherwise of the various appliances shown; their purpose is fully explained together with the best methods of fixing, and a fund of useful information relating to weight of pipes, gradients, and capacity is given. Mr. Jensen, in fact, sets forth the general details of the drainage and sanitary plumbing work of a house as it should be done in the light of the best modern practice.

The second book, on By-Laws, a first edition of which was originally published in 1901, has been brought up to date and includes a notice of the Metropolitan Management Acts which came into force in 1903. The authors have evidently very carefully studied each individual by-law, as their annotations testify. We are first given the by-law in its bald, not to say repellent, form. Then by the aid of pen and pencil there are shown the probable reason for its creation and its possible interpretations. There are in all 23 by-laws. Other subjects there may be that are more exhilarating, but we have conscientiously read through the book and can confidently recommend it, especially to those who are daily employed either in endeavouring to conform to, or to avoid, these by-laws, and who, like many of us, experience a difficulty in grasping the inner meaning of the legal prolixities in which such documents abound. In a work of this kind the reader does not look for anything startling, but there are some interesting side lights which appear as notes and enable comparisons to be made between the by-laws of the several large towns, as Dublin, Liverpool, Birmingham, Manchester, and so on, and those of London. Some of these by-laws would seem to require speedy revision. For instance, under By-law 8 no privy may be constructed within 20 feet of a dwelling house, public building, or one used for manufacturing purposes. In Manchester, Birmingham, and Dublin the distance is 6 feet only, and in Belfast 4 feet. Also, whereas By-law 7 restricts the cubic capacity of such receptacle to 2 cubic feet, Birmingham permits a capacity of 40 cubic feet and only insists on its contents being removed at three months' intervals, while Dublin limits the time to a week and the capacity to 9 cubic feet. Under By-law 9 no privy may be constructed within 100 feet of any well, spring, or stream of water used, or likely to be used, by assistance are required he should consult on equal terms with the physician at the bedside, and the investigations to be made or the treatment to be adopted should be the joint result of their deliberations." This, to my mind, grants all, and more than all, that the pathologist desires. I say more than all, because Dr. Fowler includes the treatment to be adopted in the scope of the consultation. Now, advice as to the nature of the investigations to be undertaken and the conclusions to be drawn from the results is obviously within the province of the pathologist, but advice as to treatment seems to lie outside his functions except in so far as he is a medical man as well as a pathologist, and that possibly his work has made him specially qualified to speak with regard to some particular disease. I think Dr. Fowler had in his mind a much more serious competitor of the practitioner than the mere pathologist. I mean that recent product of laboratory specialism, the immunisator—the Frankenstein monster who has been described by its maker as sitting armed with syringe and phial of bacterial emulsion ready to inject all and sundry. There is no doubt that the demonstration of opsonins in the serum and the practical applications of methods for their estimation has had a very great influence on recent methods of diagnosis and has thrown much work on clinical laboratories. It is work of such a highly technical kind that it has inevitably passed out of the hands of the practitioner into the sphere of the laboratory. The further development, too, of vaccine treatment, developed on the basis of control by the estimation of the opsonic index, has thrown fresh work and fresh power on to the laboratory. Till lately the laboratory has been the handmaiden of the ward, but in this latest development in its present phase the balance has been reversed and the laboratory has become the preponderating partner and consultation has ceased to be merely desirable and has become necessary. It is possible, as Dr. Latham is attempting to show, that a clinical method of control may be substituted for the control by the opsonic index, but the vaccine method of treatment will still lie largely with the laboratory. It has been suggested that the immunisator is the physician of the future. A very small object will obscure the sun if held sufficiently near the eye, and it would seem to me that there is a want of perspective in this view. The physician is a product of the wards, not of the laboratory. All disease is not infective, nor are microbes the be-all and end-all of pathology—the ferment is already rising above the horizon and threatening the supremacy of the germ, and there are still regions where errors in cell metabolism play the principal rôle. It seems, however, that specialism will still further develop; there is no longer room for a Teufelsdruck as professor of things in general, and indeed I seem to see sooner or later the establishment of a still further branch, a kind of information bureau required to keep the specialists in touch amongst themselves and to counteract the present centrifugal forces. There is no doubt loss in these divisions, but they seem inevitable, and our efforts must be to make the loss as small as possible.

Of one aspect of the laboratory I have said nothing—its influence by research on progress. This, of course, is its highest function, its birthright which it must not exchange for a mess of pottage. I have said nothing because the advance made during the 30 years we have been considering is eloquent as to the quantity and the quality of the research work done and of the practical services which have been rendered by observations which seemed at one time to have but a theoretical interest. But this is the view of the man in the street—the theoretical interest is the important one, for it is on the thread of theory that the pearls of progress are strung. There is, however, room for ever more work in this direction, and I do not think the advantages of the hospital have yet been utilised to their fullest extent. It is difficult to imagine conditions more favourable for the solution of many problems of disease than those which obtain in a large hospital furnished with efficient laboratories, and willing workers. The stumbling-block has been the excess not the want of material, an excess which has meant that routine work has filled the day and left but scant time for investigation. It is the old difficulty of finance and the birthright bartered for the pottage. The liberality of the citizen in America and the enlightened statesmanship of continental governments have provided a way of escape which we seek with small hope in this country. Still, even here, commerce has not proved so blind or so parsimonious as our politicians. In what direction are we to look for advance. Some improvement may be made in the machinery of research and chiefly in mutual coöperation of workers, and the past few years have seen the development of collective investigation which in the case of cancer has become international. The line of scientific advance seems to lie in the regions of biochemistry which has been progressing steadily and without any sensational discoveries. The chemist was slow to rush to the attack of problems with which physiological chemistry did not fear to deal. Slowly during the period we have considered solid foundations were laid on which a sound superstructure of knowledge has been built, and the chemist, on the basis of synthetic methods, can now do much more than guess at the composition and constitution of complex organic substance and even of proteid itself. The prevailing theories of immunity are biochemical, and metabolism and function are explained on chemical lines. We have vision, too, of a modern therapeutics widely different from the empiricism of the past. The advances we have witnessed give us sure and certain hope of still more rapid advances in the future, and though we shall not live to see the abolition of disease and suffering, still we may each from our own Pisgah top catch glimpses of the promised land.

ST. MARY'S HOSPITAL.

INTRODUCTORY ADDRESS BY SIR JOHN F. H. BROADBENT, BART., M.D. OXON., F.R.C.P. LOND., PHYSICIAN IN CHARGE OF OUT-PATIENTS.

After a few words of welcome to new students Sir John Broadbent said: It is not the quantity of study or the amount of reading you get through which are important but concentration of the mind on the subject you are trying to master and the ability to make practical use of the knowledge you acquire. Some men will sit down in front of a book and read page after page, comforting themselves with the assurance that they do so many hours' reading a day, and yet when the time comes for them to put down on paper what they think they have learnt they fail dismally. Others may attend lectures and demonstrations and yet fail to pass examinations when the time comes. I believe that this is in many instances due to the fact that they do not make abstracts of the matter they read or take any notes at the lectures they attend. It is given to few to assimilate knowledge by mere abstract auditory and visual impressions, so much so that "in at one ear and out at the other" has passed into a proverb. These visual and auditory impressions are only the way in for what may or may not be stored up as knowledge, but if you make abstracts of what you read and take notes of what you hear you call into operation a further intellectual process, the motor side of the sensori-motor mechanism of the brain, whereby you are compelled to think for yourselves, a procedure which is somewhat neglected in these days when everything is made easy and prepared for you by countless lectures, demonstrations, tutorial classes, and coaching of every kind. I think that this opsonic process if applied too freely to the mental pabulum is liable to debilitate the mental digestion which, like the physical, requires a stimulus and plenty of hard work to keep it in good order. As Gibbon puts it, "Every person has two educations, one which he receives from others, one, *more important*, which he gives himself." By all means make use of the help which is provided but do not consider it a substitute for the work you should do for yourselves. The best way of acquiring medical knowledge is to study a case in the wards, so that by daily observation you become familiar with the aspect of the patient; to note carefully for yourselves the various physical signs and symptoms which may be present, how they change from day to day and affect the prognosis, and above all not to neglect the opportunity, when occasion offers, of observing in the post-mortem room the pathological changes to which the disease has given rise. Do not be content with merely taking notes in the wards but make a copy of them in your own clinical notebooks, reading up at the same time an account of the disease in some medical text-book. Then add as a supplement to your notes a brief summary of the points in which the case you have been watching differs from a so-called "typical" case. You will thus have a clear mental picture or object lesson of the

We cannot agree with him that bony ankylosis never occurs in tuberculous disease in childhood; it is certainly rare but specimens of it exist in museums. The book is ably written and it should prove of interest to all who have to deal with tuberculous disease of the hip-joint.

A Text-Book of Minor Surgery. By EDWARD MILTON FOOTE, A.M., M.D., Instructor in Surgery, College of Physicians and Surgeons, Columbia University; Lecturer on Surgery, New York Polyclinic Medical School, &c. Illustrated by 407 engravings from original drawings and photographs. London: Sidney Appleton. 1908. Pp. 752. Price 21*s.* net.—Minor surgery includes nowadays many surgical procedures which at one time were looked upon as major operations, but the progress of surgery has made them of less severity and importance. The ordinary text-books often devote attention mainly to the more serious operations, yet the general practitioner has much more interest in the simpler common conditions with which he will have to deal. The book is lavishly illustrated; the illustrations are very good and in nearly all cases they show what they are intended to show. We can commend the work to the attention of junior practitioners who need some help in dealing with the ordinary surgical cases which come to them.

Climate, Considered especially in Relation to Man. By ROBERT DE COURCY WARD. With illustrations. London: John Murray. 1908. Pp. 372. Price 6*s.*—The most interesting chapter to medical readers, at all events, in this clearly written work is that entitled "The Hygiene of Zones" (Chapter VII.). In this chapter the author points out the complexity of the subject and explains the difficulties of establishing the exact relationship between climate and disease. Untrustworthy statistics are often at the root of this difficulty, while there are factors, such as sanitation, food, water, and so forth, which, of course, have an influence on the health of a community. The modern view, however, is that the cause of disease may no longer be traced directly to meteorological conditions but to the effects, more or less direct, of these conditions upon the micro-organisms which are the specific cause of the disease. As the author points out, atmospheric conditions may help or may retard the development of the micro-organisms and may strengthen or weaken the individual's power of resistance against the attacks of the germs. Further, Sir Patrick Manson has pointed out that in the case of malaria the mosquito is not only a vector but serves also as a medium in which the germ undergoes certain developmental changes necessary for its existence as a species, as well as for its successful introduction into a fresh human host. After this generalisation the author deals with various diseases and the kind of places in which and when they are prevalent. Further chapters deal with the changes of climate, the characteristics of the zones, and the classification of climates. He does not omit to mention the observations of the old Greek philosophers or to make reference to the attempted classification at relationships between climate and disease outlined by Hippocrates. The book furnishes a very interesting and readable contribution on the subject.

The Radio-active Substances: Their Properties and Behaviour. By WALTER MAKOWER. London: Kegan Paul, Trench, Trübner, and Co., Limited. 1908. Pp. 301. Price 5*s.* —At this stage in the history of radio-activity the want is felt of a text-book giving a clear and straightforward account of the phenomena and theories concerned so far as recent developments have gone. The discovery of radio-activity has, in fact, opened up a new branch of science which it cannot be doubted is going to be of some importance to medicine. We are satisfied that the book before us supplies a need and the author happily does not fail to realise the difficulties which face the student who for the first time approaches the subject. We need hardly point out that this student must often be the medical man in active practice who therefore has no time to go into undue detail and who, in fact, requires a clear, concise, and practical account of the position reached by recent studies of the subject. This book serves as an admirable and intelligently written introduction to the study of radio-activity. The subject is beset with some difficulties in regard to making it clear, but the author knows quite well the points which need the careful treatment by which they are made intelligible. He has avoided so far as possible the use of mathematics, and in those cases where the application of mathematics cannot be ignored he has used homely illustrations to help the reader to a clear appreciation of the theories involved. We cordially commend the book to those who would keep pace with the developments of this most interesting branch of scientific study.

The National Physique. By A. STAYT DUTTON, L.R.C.P. Lond., M.R.C.S. Eng. London: Baillière, Tindall, and Cox. 1908. Pp. 188. Price 5*s.* net.—Mr. Dutton has been engaged in practice during 15 years in no less than 50 districts of England and Wales, including 12 in London, and has been so struck with the apparent prevalence in all of them of a common disease that he set himself to collect convincing evidence thereof and this book is the result of his inquiry. The disease in question is anæmia of the chlorotic type and his research has consisted in the estimation of the hæmoglobin in a large number of nominally healthy persons of various ages who were living their ordinary lives, his subjects being chosen at random chiefly amongst the working classes. In the first part of his book he records the results of these investigations which showed in almost every district that a considerable preponderance of people tested had a hæmoglobin percentage of between 10 and 20 below the normal, whilst many others had still poorer blood; the deficiency was more marked as a rule in boys than in men. On these premisses Mr. Dutton founds longer chapters which deal with the causes and prevention of physical deterioration, army recruiting, and prevalent diseases in connexion with the blood, from which it is clear that he subscribes whole-heartedly to the oldest of all physiological maxims, "The blood is the life." In the physical degeneration which he acknowledges to be a national danger he sees anæmia writ large, and though his book shows some signs of the special pleader we should not like to assert that he is altogether deceived. The connexion which he declares to exist between anæmia and imperfect physique would certainly have been more convincing had he given us some information concerning the weight and measurements of the people whose blood he examined, and until he has made some such systematic comparison he can be hardly said to have proved his case. The argument that because he finds anæmia very prevalent in a nation which is suffering from physical degeneration these two facts have a causal relationship might be appropriated by another who should desire to prove that any disorder of frequent occurrence, such as dental caries or dyspepsia, was responsible for deterioration in the national physique. Mr. Dutton has, however, written a suggestive little book and he is to be congratulated on having found time and inclination for a laborious piece of research in the exercise of an amazingly ubiquitous practice. It is not everyone who uses exceptional opportunities in so practical a manner.

The Solar System: A Study of Recent Observations. By CHARLES LANE POOR. With illustrations. London: John Murray. 1908. Pp. 310. Price 6*s.* net.—This book deals with an obviously wide subject but the author, while admitting that many interesting matters have had to be omitted, has succeeded, we think, in giving an impressive account of the results brought to light by modern methods sufficient funds may be forthcoming to provide assistance for dependants while the breadwinner is undergoing treatment. The institution is not intended to interfere with the work of existing institutions or that of the medical practitioner, but rather to work in coöperation with them. No patient would be treated or allowed to attend the institution who could afford to pay a doctor, or who is attending a hospital, or who is or has been under the care of a medical practitioner without the written consent of the doctor whom he has consulted.

[Turning from this subject the speaker devoted much of the remainder of his address to the dental needs of the poor. After describing the magnitude of this evil and the urgency for a remedy from the point of view of the national health, he deprecated Mr. J. G. Turner's suggestion of the levy of a special dental rate and advocated that the dental departments of the general hospitals should undertake the filling of teeth and the supply of dentures, and that similar departments should be added to the provident dispensaries. The dental inspection and treatment of school-children and their instruction in the use of the tooth-brush were of the first importance. Sir John Broadbent then concluded with the following words:]

There is one other point I should like to touch upon. In the out-patient department we see many distressing cases in which the breadwinner, though seriously ill, is unwilling to give up his work and come into hospital for a time, though the rest and treatment there afforded might avert a fatal issue, as he says that this would mean starvation for his wife and family. To give one or two instances which have recently come under my notice. A hansom cab driver with serious heart disease (aortic incompetence with failing compensation) insisted on continuing to drive his cab in spite of warnings, to the great peril of its occupants as well as himself, as he was liable at any time to drop down dead. A stableman with advanced dropsy refused to come into hospital for treatment which would have afforded immediate relief. A window cleaner with an internal cancer persisted in following his occupation, though he was so weak he could hardly stand (a pleasant prospect, this, for the uninsured householder). These are instances out of many of the dilemma in which the really plucky working man is placed by illness, and I should like to see the hospital in touch with some charitable agency so that some provision could be arranged for the support of the wife and family while the breadwinner is temporarily incapacitated. I am sure there would be little difficulty in raising a special fund for the purpose and I think that some charitable agency, such as the Charity Organisation Society, would be only too glad to act as almoners to the fund. In these days when so much is done for the unemployed, for whom work and a comfortable berth at a farm colony are provided by public subscription, I think it is time that something should be done for the genuine working man who, by no fault of his own, is temporarily incapacitated by illness.

LONDON SCHOOL OF MEDICINE FOR WOMEN.

INTRODUCTORY ADDRESS BY H. SAINSBURY, M.D. LOND., F.R.C.P. LOND., SENIOR PHYSICIAN TO THE ROYAL FREE HOSPITAL.

Dr. Sainsbury took for his subject "Some Points of Importance in the Study and Pursuit of Medicine." After some opening remarks inculcating earnestness of study he warned his students against too early specialisation in either medicine or surgery, which great branches should be regarded as complementary and not antagonistic in their aims. He proceeded:—If I were asked to define medicine and surgery I should, whilst disclaiming any pretence at a sharp demarcation of sciences which touch and blend at so many points, describe medicine as applied physiology and surgery as applied anatomy. I mean by the latter expression living anatomy—i.e., the living, working organs and systems; but you will say this is physiology, and so it is, and thus at the very outset my attempt at separation breaks down. And yet I hold a very definite conception which I must try to convey; this living anatomy is structure on a *large* scale and function upon a correspondingly large scale, and in this grosser functioning, from the surgical standpoint, the topography of the organs and parts assumes a predominant importance, and hence the anatomy of death—i.e., the structural relationship of the parts at a standstill—is so essential a study. Give yourselves enthusiastically to this study, look intelligently at the facts of structure which you discover, and try in your mind's eye to bring them back to life and see them not in static but in dynamic equilibrium. Then consider why it is that you are prying into these intricacies of working and having found the answer, viz., in order that when the occasion comes you may safely enter this structural maze, interfering without deranging, or at least at a minimal cost of disturbance; having this answer in mind, look at your facts from the practical—i.e., applicable—side, always thinking how might this piece of knowledge be made use of. A fact with a reason behind it appeals to the mind and is the more easily remembered, whereas a bare fact, void of particular significance, is as difficult to impress as it is hard to retain. (I speak relatively, for the facility of the unaided memory is in the case of some people nothing short of marvellous.) Moreover, mere memory is the lowest form of mental process; the mind grows least upon its exercise; it is reasoning that we want, some attempt to put and meet the everlasting "why" of Socrates. Accordingly, make as large as you can your collection of reasonable facts.

Surgery, as applied living anatomy, will provide scope for the exercise of the highest powers of the mind in diagnosis, in forecast, and in treatment, and when you come to practise, certainly if the present phase of mind persist, you will find that it casts a wide net and secures a heavy draught. Is there anything which surgery, as above defined, does not cover? Sometimes I am tempted to doubt whether there is (I am talking, of course, of practice, there being no lack of medicine in the text-books), for the physician's remainder, after the surgical net has been cast and drawn, shows a remarkable paucity of fish and such as they are they run rather fine. And yet, and yet, medicine is a noble study and I would not change it if I had to begin all over again. Possibly, also, readjustments may in the future make their appearance sufficient to satisfy that modicum of the *auri sacra fames* of which the physician stands possessed, for as the obstetric physician has in self defence become the obstetric surgeon it is possible that the chest physician may come to think that chest surgery should be his also, and so forth. These are horrid suggestions and I apologise for making them, and in requital will offer this consolation that should such things come to pass we shall then all be specialists, each in his own department, practising both medicine and surgery; the reconcilement of the physician and surgeon will then be complete, the lamb and the lion united in one person will thenceforth lie down and uprise together. But whether we separate medicine and surgery or unite them in the person of one practitioner it matters not a whit—in the main they are quite distinct in their spheres of activity. The surgeon may claim more and more of the grosser structure and functioning of the body: he may say, "This organ is mine or at any rate I demand my share in it"; nay, he may claim even this cell cluster and this cell tract. Driven from pillar to post, always in retreat, the physician will make his final stand and say, "But the cell is mine, its powers, its potentialities are mine; away with knife and forceps, make room for my armamentarium." The chemist is telling us that the time-honoured theory of the elemental atom as an irreducible, unchangeable, material minimum no longer holds, that conceivably the atom may be raised or degraded up and down through the Mendeleef scale. Conceivably, perhaps, actually remotely possibly, even so will not the Daltonian atom as a material minimum still continue to play the chief part in the practical politics of chemical changes? I ask the question, having no authority to do more. In like manner though it were vain to forecast the future pronouncements of the physiologist in respect of the biological cell, yet may we not take it that in the practical politics of biology it stands now and will stand in the future for the irreducible structural unit? Here, then, we shall make our stand, intrenching ourselves behind its powers *in esse* or *in posse*. Good generalship, however, requires that there should be a hinterland of some sort at the back of even a last stand, and so, as the surgeons are an enterprising race, let me remind you, embryo physicians, that there are still the nucleus and the nucleolus upon which to fall back, good rallying points whence to hurl defiance at the pursuer before making good your retreat into the physico-chemical fastnesses of changing molecules and vanishing atoms and vanished fees; there you will be allowed to flounder in peace.

THE LANCET.

LONDON: SATURDAY, OCTOBER 10, 1908.

The Introductory Addresses.

AT the beginning of October in each year there arises a flood of oratory issuing from most of the medical schools and intended to assist the medical student on his onward course. Some of the medical schools, however, have discontinued the custom of an introductory address, the advantages or disadvantages of which we need not now discuss. When the number of medical schools is considered it is not surprising that the same subjects are often dealt with year after year. At the same time there is a really remarkable variety in the matters discussed and in each recurring October we find fresh illumination on the many problems of medicine.

The Huxley lecture, which is delivered biennially at Charing Cross Hospital, deservedly holds a high position among the introductory addresses, and the lecture delivered by Sir PATRICK MANSON dealt very felicitously with the important subject of tropical medicine which he himself has done so much to advance and to bring to its present high state of perfection. He showed that while many of the diseases with which we are acquainted in temperate climes are also known in the tropics there are various diseases peculiar to warm climates. Most of these tropical diseases are caused by organisms which require a high temperature for their successful passage from host to host, or which need animal intermediaries which flourish only in high atmospheric temperatures. As these conditions only occur in tropical or subtropical countries the diseases produced by germs or parasites such as these can arise and spread only in warm countries or in warm seasons. A living intermediary is needed in malaria, yellow fever, trypanosomiasis, and filariasis. In ankylostomiasis no intermediate host is required, but the parasite needs a warm moist nidus for the development of the egg. It is thus clear that for the study of tropical diseases much knowledge is required not needed for most of the pathology of temperate climates. As Sir PATRICK MANSON mentioned, a school of tropical medicine should include a protozoologist, a helminthologist, and an arthropodologist in addition to the usual lecturers. Most tropical diseases are due to protozoa or helminths, and therefore the assistance is needed of those who have specially studied these branches of zoology. The intermediary hosts of these pathogenic protozoa and helminths are nearly all insects, ticks, or crustaceans and therefore the services of an arthropodologist are required. Sir PATRICK MANSON presented a table showing all the known diseases which may be called tropical, with the causative agents to which they are due and the mode in which transmission occurs, and the list was remarkably long. We do not remember to have seen a better presentation of the importance of the diseases of warm countries or a more powerful plea for their adequate study. At the Victoria University, Manchester, Sir T. CLIFFORD ALLBUTT spoke mainly on hospital management. He urged the necessity of the recognition of the fact that the members of the medical staff of a hospital are not the employees of the hospital board but they should be looked upon as equal partners in the management of the hospital. It is not uncommon to hear the benevolent services of a hospital staff depreciated on the ground that its members are paid by the opportunities, reputation, and fees which their position carries with it, and Sir CLIFFORD ALLBUTT showed that this is very far from being true. He spoke of the great value of pathology and suggested that pathological laboratories should be more closely connected with the wards than is generally the case. Lastly, he showed that medicine is now beginning to take its true place in the State, and he urged the need of the appointment of a Secretary of State for Medicine, on a par with the Secretary of State for War. He dealt with the problem of medical education and the need for a one-portal method of qualification in order that the universities may be able to devote themselves to real training and not merely to the teaching of text-books and the testing of text-book knowledge. At St. Mary's Hospital Sir JOHN BROADBENT dealt with the future of medicine and considered that although much of the present-day work of the physician might be taken out of his hands by the discovery of vaccines and serums, ample work would still remain for the physician to do in the general management of the patient and especially with regard to the treatment of such conditions as neurasthenia, where no vaccine could avail but where a general control of the life and habits of the patient would always be required. He quoted with approval the advice given by BACON in his "Regimen of Health," where he says that some physicians are "so pleasing and comformable to the humour of the patient, as they press not the true cure of the disease," while others think so much of the disease that they disregard the condition of the patient, and he advises the choice of "one of a middle temper, or if it may not be found in one man" he suggests that the patient should "combine two of either sort." The second part of his address Sir JOHN BROADBENT devoted to a consideration of out-patients. He urged that the ordinary medical treatment should be supplemented by agencies for looking after the families of patients who really need treatment as in-patients and who yet persist in continuing at their work because the cessation of their occupation would mean the starvation of their families.

At St. George's Hospital Dr. CHARLES SLATER took for his subject the importance of the laboratory in medical education and practice. He claimed a fuller recognition by the State of the value of medicine in the prevention of disease. The public and the State have been accustomed to pay for cure, but they have not yet learned that it is far better to pay for prevention and that to prevent the occurrence of disease is worth a hundredfold more, even in hard cash, than the cure of the cases of disease when they have occurred. He suggested that it is customary too often to look upon the pathologist merely as a servant of the was Willis of London, a famous anatomist. He extended the system. All bodies in nature were regarded by him as composed of three elements—spirit, sulphur, and salt—spirit being only found in quantity in animals. His application of chemistry to examination of secretions was important, especially in connexion with diabetes, but his main system soon became obsolete. The multiplicity of dogmatic schools started a reaction towards a study of disease *without preconceived* hypothesis, and the leader of this natural school, as one might term it, was the great Sydenham, who has been termed the English Hippocrates. The philosopher and physician Locke was a friend of his, and admirably sums up his good characteristics in the following letter. "You cannot imagine how far a little observation carefully made by a *man not tied up in the four* humours (Galen) or the salt, sulphur and mercury of Paracelsus, or the acid and alkali of Sylvius and Willis which has lately prevailed, will carry a man in the curing of diseases, though very stubborn and dangerous; and that with very little and common things and almost no medicine at all." Sydenham may be said to have inculcated the true scientific spirit, which was greatly required, for he seems to have maintained throughout his work an "open mind." He revived the ideas of Hippocrates regarding the *vis medicatrix naturæ*. The attitude of most of the dogmatists of that age might be said to be similar to that of the gentleman who, during an argument, was taunted with not being open to conviction. "Not open to conviction," said he with great indignation, "I am open to conviction, but—*show me the man who'll convince me!*" The following incident indicates the artificial condition of affairs in his time. Sir Robert Talbor, a noted empiric, on being admitted to a consultation with certain learned dogmatists, was asked by one of them (doubtless superciliously) "What is fever?" "Fever," replied Talbor, "is a disease which I cannot define but can cure, and which you cannot cure but can define." Talbor's cure for fevers contained cinchona bark which had been introduced not long before and was denounced by many at the time as a special invention of the powers of evil. This is merely another example of unscientific criticism, still common enough at the present day, and of the truth of the adage, "Die Menschen verhöhnen was sie nicht verstehen" (i.e., "Men despise what they don't understand"). In the eighteenth century although some good work was done the making of dogmatic systems went on. Hofmann and Stahl formed separate pneumatic or animistic systems. Cullen of Edinburgh developed a system based upon von Haller's doctrine of "irritability," and Brown introduced his "stimulus" theory known as the Brunonian system. As the result of investigation Brown concluded that some diseases required stimulating treatment and others depletion. But 97 per cent. required stimulating and therefore the treatment of most physicians from Hippocrates onwards must have been wrong, because bleeding and depletory treatment had been common, the idea being to remove morbid matter by elimination. Brown's theory caused great excitement at the time. In Scotland and Germany there were riots among the students which seems to indicate that the student of those days took his work seriously if not always scientifically. The checking of excessive bleeding has probably been of considerable importance. A large amount of work in connexion with the scientific foundations of medicine was carried out in the century. The premier position should, perhaps, be given to Boerhaave and his students. Boerhaave was professor of medicine at Leyden, and although in the hospital there only 12 beds were available for teaching, Leyden became the centre of medical influence in Europe. A student of his, von Haller, was a distinguished physiologist and anatomist. He proved experimentally that "irritability" was a property of muscular tissue, and "sensibility" a property of nerve cells, and thus undermined the animistic hypothesis. The two brothers William and John Hunter, the former of whom was on the staff of the Middlesex Hospital, had a great influence in stimulating research in anatomy and pathology. William Hunter has been described as the first great teacher of anatomy in England. Jenner, who introduced vaccination, a practice empirical at the time but now readily understood on the recent doctrine of immunity, was a pupil of John Hunter. Lady Mary Wortley Montagu had previously introduced inoculation (about 1720) which proved unsatisfactory.

The beginning of the nineteenth century produced a further crop of theories. One of the most extraordinary—the homœopathic—introduced by Hahnemann (1755–1843) survives to the present time. Hahnemann held, first, that as Hippocrates had expressed it, "*similia similibus curantur*"—i.e., like cures like—which meant that the cure for a disease is the drug which would produce symptoms similar to those of the disease in a healthy person; secondly, that diseases were spiritual dynamic derangements of the vital principle; and thirdly, that medicines became more powerful on dilution, and claimed that he had proved these principles to be true by numerous scientific experiments. He theoretically rejected the *vis medicatrix naturæ*, although his good results in many cases probably were due to the truth indicated by the term, seeing that he often used medicines in such dilution that it was almost impossible to detect by analysis that anything was present. He would take the ordinary tinctures, dilute to 1-50th, dilute again to 1-50th, and so on for 30 times. Important advances had by this time been effected in physical diagnosis. Piorry improved the percussion method for recognising diseases of the chest introduced by Auenbrugger of Vienna some time before, and Laennec (1781–1826) introduced the stethoscope. Laennec was a keen student of morbid anatomy in connexion with auscultation, so that his work as regards diseases of the chest is of fundamental importance.

In Britain by far the most important work in the first half of the century was carried out by Sir Charles Bell, surgeon to the Middlesex Hospital. Bell's work is generally regarded as the most brilliant since that of Harvey. He showed: 1. That in the main nerve trunks there are special sensory filaments which transmit impressions from the surface of the body to the brain, and special motor filaments which convey motor impressions from the brain or other nerve centres to the muscles. 2. Some nerves consist entirely of sensory filaments and are therefore sensory nerves, and others are composed of motor filaments and are therefore motor nerves, while a third variety contains both kinds of filaments—sensori-motor; in the nerves proceeding from the spinal cord, for example, the posterior are sensory, and the anterior are motor. 3. The brain and spinal cord may be divided into separate parts, each part having a separate function, either sensory or motor. Incidentally one might mention that Bell took a great deal of trouble in connexion with the formation of our medical school, his interest and generosity probably being only surpassed by that of Mr. Morris a few years ago, when the school was in danger of being completely engulfed and assimilated by the University of which it is proud to form an autonomous part. Bell's work has been followed up by Marshall Hall (1832), who has been called the discoverer of the "reflex nervous system," Abercrombie, Broca, who discovered the centre of speech (1861); Brown-Séquard, Bastian, Ferrier, Charcot, Romberg, Golgi, and others have worked out results of great importance in connexion with clinical diagnosis and surgery of the brain in disease, since successfully applied by Lister, Horsley, Macewen, and others. Much further important work was done in the first half of last century, associated with the names of Bright, Addison, and Stokes in England, Rokitansky in Austria, Schonle in Germany, and many others. In 1839 Schwann published his epoch-marking cell theory, in 1859 Darwin published his "Origin of Species," and in 1860 Lord Lister published his theory of asepsis, founded upon the brilliant work of Pasteur.

It is difficult to overestimate the incalculable benefits which the Listerian system has conferred upon humanity. Taking an approximate average for the more important hospitals in Germany and in this country prior to 1860 the mortality in operative surgical cases was 40 per cent.; it is now under 3 per cent., notwithstanding that operations which no surgeon would have dared to attempt before 1860 are now commonly performed. In connexion with the Listerian antiseptic treatment might be mentioned the introduction of zinc chloride as an antiseptic in certain cases by Campbell de Morgan of the Middlesex Hospital. This is of interest because recent experiments in connexion with the ionic treatment (to be mentioned presently) have shown that the zinc ion is the best coagulating agent known in medicine.

Unfortunately time does not permit of one's giving even a *résumé* of the advances made in connexion with the application of physics to medicine. The Roentgen rays, the high-the post as a stepping-stone to other and more lucrative positions upon the staff. He alleges that there is little inducement for seasoned workers in the field to compete for the appointment of anæsthetist because they receive no adequate status and their work is brushed aside as being of scant value. Thus, we are told, anæsthetists do not enjoy the privileges accorded to physicians and surgeons, to assistant physicians and assistant surgeons, and to officers such as surgeon-dentists who control special departments. "A Hospital Anæsthetist" complains that surgeons ignore the usual amenities which should exist among colleagues, and in the case of the anæsthetists dictate to them what they should do and withhold from them alike courtesy and appreciation of their special knowledge of their department. The natural result of this, we are asked to believe, is that the public as a body do not hold the anæsthetist in much repute and are not encouraged by consulting surgeons to call him in as an expert when dangerous or critical operations have to be faced. The surgeon is sought with care while the anæsthetist is chosen at haphazard is practically the complaint of the writer to the *Times*. The view is much the same as that expressed by Dr. HEWITT. He considers that the *personnel* and the system of teaching at some hospitals are capable of improvement, and circumstances can hardly have failed to bring home to the minds of all of us that in some instances there is a lack of organisation in this department. This has led to public comment and undoubtedly a vast amount of misapprehension exists upon the subject of anæsthetics, the bulk of the public being unaware of the importance of the work of the anæsthetist. It is usual to hear of the wonders of modern surgery and the triumphs of the scalpel; how often is it recognised that a skilled and experienced anæsthetist has fought for his patient's life through a weary hour or more and has enabled his eminent colleague the surgeon to accomplish another victory? For the sake of the patient the potential dangers of the anæsthetic are minimised, and in some cases this may lead to the anæsthetic being given by men sound, no doubt, in the knowledge of their profession but lacking in a scientific grasp of the facts underlying the rules governing narcotism. It may happen that such men undertake the duty reluctantly and only yield to the entreaties of a nervous patient who dreads the advent of a stranger, while it is not recognised by the public that a rule-of-thumb knowledge of anæsthetics is not skilled anæsthetisation.

While all are agreed that medical students ought to be taught more fully the recognised methods of administering anæsthetics, the amount which they should be taught and the due relations of the specialist anæsthetist to the general practitioner make up between them a most delicate question. To administer anæsthetics with complete knowledge in difficult cases and with the absolute minimum of risk demands scientific knowledge and judgment begotten of experience—those who can do it ought to be held in the same regard at their schools and hospitals as any other specialist attached to the institution. But for this very reason every medical student cannot become an anæsthetist of this class; he cannot in the present state of the curriculum spare the necessary time for the training, he may lack opportunities for the teaching, while he may not have the individual aptitude for an arduous and responsible branch of his profession. All that can be done for him, as yet at any rate, is to see that he is thoroughly grounded in the principles of giving anæsthetics in uncomplicated cases, and the specialist anæsthetists will no doubt approve of such a man giving anæsthetics, if only because it is he whom the public will in many cases employ. There are vastly more operations, large and small, where anæsthetics are used than it is possible that any specialist class could cope with, while rural neighbourhoods, towns of under 5000 inhabitants, and parochial authorities cannot possibly support the services of a member of such a class. For the present all th can be done is to make the teaching in anæsthetics at a our schools thorough, to insist upon all students learnin the principles of the administration of anæsthetics as compulsory subject, to raise the position of the anæsthetis upon our hospital staffs to that of the other members of th honorary staff, and to trust that such reforms will result i the diffusion of generally adequate skill.

◆

The Health of the Army.

THE Army Medical Report for the year 1907 recently issued has excited more than usual general comment. This is probably due to the fact that during the present period of reorganisation and transfiguration of our land service military affairs have aroused greater interest than they do normally in the public mind. The medical organisation of our army has come in for its share of this increased attention, with the result that the public is able to realise with PLATO the importance of the influence of the physician in matters of State. The report deserves the wide comment that it has obtained, for it bears record to good and careful work on the part of this department and enables us to perceive that a deep debt of gratitude is due to the men of science and men of affairs—amongst whom SIDNEY HERBERT and EDMUND A. PARKES are the most famous—who after the Crimean war founded, in the face of strenuous opposition, the Army Medical School. One section alone of the present report affords a triumphant vindication of the foundation of that school—namely, that which deals with the almost complete stamping-out of "Malta fever." This fever but a few years ago was a mysterious disease of unknown origin, levying a heavy toll on our regiments, and it may be counted one of the greatest victories of modern science, systematically equipped and organised, in general, and of the medical department of the army in particular, that this toll will no longer have to be paid. The official statistics proving the reality of this triumph of therapeutics have been so recently before our readers that we need not recapitulate them here.

We publish in another column an abstract of the report on individual diseases as they affected the troops in 1907, but it will be convenient now to draw attention to two outstanding causes of sickness in the army. The amount of venereal disease appears always to vary in every part of the world from various reasons, some easily traceable, and others unknown. It is a matter of great regret that the entries for 1907

with improvement, both as regards variety of food and cooking, which cannot fail to affect favourably the general health of the men. As we have pointed out before, it will be practically impossible to do so well in very small craft, torpedo boats, and so on. Here, however, we have no doubt that the practical adaptability to environment of the "handy man" will assert itself and the best possible be made of surrounding circumstances. Compared with the dietary of his predecessors the *menu* of the modern blue-jacket is a *menu de luxe*, at any rate in large ships, where it has been found possible to adopt the general mess system, although, as we stated in a leading article last year, we regret that the meat ration was reduced. Earnestly desiring, as we do, the welfare and progress of the Naval Medical Service we hope that some other reforms which we have suggested recently may soon follow and that some of the best stamp of young medical men may be attracted to the Service afloat.

HISTORICAL ASSOCIATIONS OF ARSENIC.

IN a series of articles in the *Pharmaceutical Journal* Dr. J. Gordon Sharp deals in an interesting manner with the history of arsenic from the time of Hippocrates (B.C. 460–357) to the present day. Geber was the first to prepare white arsenic in Europe in the eighth century, at a time when the diabolical art of poisoning was becoming popular as a means of removing a foe or rival. Arsenic was eagerly welcomed by the poisoner owing to its solubility and freedom from odour and taste, and it was most extensively used for nefarious purposes during the fifteenth and sixteenth centuries. It was through arsenic that the Borgias attained their unenviable reputation, and so great was the fear of it that makers of antidotes and amulets drove a thriving trade. In Italy two women acquired notoriety as poisoners during the seventeenth century, Tofana, after whom a solution of arsenic was named "Acqua Tofana," and Beatrice Spara, whose pupil Exili afterwards became suspected of being concerned in many cases of poisoning that had occurred in Rome and fled to Paris. There he founded his art and became the first of a long series of professional poisoners. One of his pupils, Sainte-Croix, passed on the knowledge to his inamorata, Marie Marguerite d'Aubray, afterwards wife of the Marquis de Brinvilliers. This base woman visited patients in the Hôtel Dieu Hospital at Paris in the guise of charity with the object of poisoning them by arsenic, and subsequently poisoned her father and two brothers. Among other pupils of Sainte-Croix were Penautier, treasurer of France, and Cardinal de Bonz, both of whom employed their knowledge to remove those who stood between them and their ambition. The unholy trade was then carried on chiefly by midwives, nurses, perfumers, and fortune-tellers until well into the eighteenth century. Poisoning has never been popular in the British Isles, so that very few cases of poisoning by arsenic have been recorded. In the Middle Ages men were terror-struck because no test was known for the recognition of this deadly agent. This reproach was removed when Black, the celebrated chemist, in 1752, at the trial of Mary Blandy, gave two tests for arsenic—viz., by reduction to the metallic state by heating with black flux in a tube, and by deposition of the element on copper. Afterwards Orfila (1787–1853), Christison, Alfred S. Taylor, Casper of Berlin (1796–1864), and the late Sir Thomas Stevenson helped to establish toxicology on a firm basis and placed the detection of minute traces of arsenic beyond dispute chiefly by the aid of Reinsch's and Marsh's tests. It is not known with certainty who was the bold individual who reasoned that there might be some valuable remedial properties even in the deadly "Acqua Tofana" if administered in suitable doses. Dr. Sharp hazards the opinion that Thomas Goddard (1617–1674), one of Cromwell's physicians, was among the first to employ it in medicine. His view on the subject would appear to have been noised abroad, with the result that several remedies were sold, at first secretly and then openly, for the then universal affection—ague—under the names "tasteless ague drops," "Asiatic drops," and "Asiatic pills." Authentic history of the medicinal use of arsenic, however, commences with Fowler's solution. In 1786 there appeared a small work[1] by Thomas Fowler, M.D., physician to the general infirmary of the county of Stafford, wherein he described how he was led to introduce the preparation. A specific for ague, under the name "tasteless ague and fever drops," was being used in the Stafford Hospital and Dr. Fowler and Mr. Hughes, the apothecary, identified it as an arsenical preparation. After many trials they succeeded in devising the formula which bears Dr. Fowler's name, and it was officially recognised in the London Pharmacopœia of 1809. The formula for Donovan's solution of arsenic and mercury was first published in the *Dublin Journal of the Medical Sciences*. It is of interest to note that atoxyl was first prepared by the French chemist Béchamp in 1863, but its medicinal properties do not appear to have been studied until the last few years. Its employment in sleeping sickness was suggested by the known usefulness of arsenic in protozoal diseases, following the treatment of David Livingstone who recommended arsenic in tsetse fly disease. Syphilis is now looked upon as belonging to the same category of diseases and atoxyl is being employed in the treatment. Evidence has been brought forward to show that the favourable results obtained with atoxyl in these diseases cease after a time but that they are renewed by administering mercury.

JEWISH LYING-IN MOTHERS OF THE WORKING CLASS IN FRANKFORT AND IN THE EAST-END OF LONDON.

A CORRESPONDENT writes referring to the articles now being published in THE LANCET upon the care of infants in London: "I see that allusion is made to the question of mothers who are expected to go out to work shortly after childbirth, and the suggestion is, of course, put forward that in some instances the mother, who should be lying-in, is compelled by the exigencies of the situation to get up and to work before she is in a fit state so to do. It is, indeed, said to be a matter of more or less common knowledge that one of the reasons why so many babies of the working class are artificially fed is because the mother is not able to take a long enough rest during the lying-in period, the consequence being that the breast milk dwindles or becomes impoverished." We are not quite prepared to accept this large deduction from admitted facts, but it appears that in England, except among certain of the Jewish communities, no steps have been taken to permit the working mother to have a sufficient rest after child-bearing. In a paper read by Miss M. le F. Boileau before the National Conference on Infantile Mortality held in London in the spring of this year there was described a system in vogue in Frankfort for supplying help to poor mothers during the lying-in period or illness. A register is kept of such female helpers as wish to hire themselves out for housework in cottage homes in those cases in which the mother is unable to attend to her own work, and a committee of women manages the organisation. The female helper is required to fulfil all the duties that fall to the lot of a housewife, but she cannot minister to the very poor as branch of the vagus to the glosso-pharyngeal and thence *viâ* the nerve of Jacobson. Poirier describes the sensory nerve for the external auditory meatus (Arnold's nerve) with the branches of the facial, and points out that it presents considerable diversity in the arrangement of its connexions with other nerve trunks: Ordinarily it is connected with the vagus, but it is sometimes connected with the vagus and with the glosso-pharyngeal, and sometimes with the glosso-pharyngeal alone. Arnold's nerve is generally connected with the facial three or four millimetres above the stylo-mastoid foramen. Cunningham states that Arnold's nerve usually communicates with the facial nerve by a branch arising from the latter in the aqueduct of Fallopius. In rare instances Arnold's nerve is connected with the trunk of the glosso-pharyngeal below the ganglia. Cruveilhier, Richet, and Testut have seen a nerve pass directly from the base of the tongue and the soft palate to the facial at the stylo-mastoid foramen without joining the glosso-pharyngeal. This nerve may prove to be the nerve of taste from the posterior third of the tongue which ordinarily, but not always, is, for part of its course, included in the sheath of the glosso-pharyngeal.

---

[1] Medical Reports of the Effects of Arsenic in the Cure of Ague, Remittent Fever, and Periodic Headaches. 1786. London: J. Johnson, 77, St. Paul's Churchyard.

The sensory division of the facial conveys, in addition to taste impulses, impulses of common sensation from the skin of the posterior half of the external auditory meatus and part of the concha. On division of the sensory trunk of the fifth nerve behind the Gasserian ganglion the sensation of the external auditory meatus and of part of the concha remains normal. Ramsay Hunt, in an interesting communication in the *Journal of Nervous and Mental Disease* last year, points out that inflammation of the geniculate ganglion causes herpes within the auricle and external auditory canal. Inflammation spreading from the geniculate ganglion along the sheath of the facial nerve explains why facial palsy and various auditory symptoms sometimes accompany herpes auricularis. The "zoster zone" of the geniculate ganglion lies between that of the Gasserian ganglion and that of the second and third cervical ganglia.

The operation described in this paper brings the distressing symptoms induced by certain forms of internal ear disease within the control of surgery, in that such symptoms may be cured by division of the auditory nerve just as epileptiform tic in the territory of the fifth nerve is cured by dividing the nerve or removing the Gasserian ganglion. Just as in division of the trunk of the fifth nerve we may hope some day to be able to spare the motor root, which is in no way concerned in the disease, so in division of the auditory nerve we may hope to be able to spare the nerve of Wrisberg which is in no way concerned with auditory symptoms. Labyrinthine symptoms have their origin in the cochlear ganglion or in the vestibular ganglion or in both ganglia, but we cannot yet think of a method for separating surgically the cochlear and vestibular divisions of the auditory nerve so as to be able to spare the one or the other as the symptoms may indicate.

Harley-street, W.

THE SERUM TREATMENT OF CEREBRO-SPINAL FEVER IN THE CITY OF GLASGOW FEVER HOSPITAL, BELVIDERE, BETWEEN MAY, 1906, AND MAY, 1908.

By J. R. CURRIE, B.A. OXON., M.B. GLASG., D.P.H.,
ASSISTANT MEDICAL OFFICER OF HEALTH, CHESTER; LATELY SENIOR ASSISTANT PHYSICIAN, BELVIDERE FEVER HOSPITAL, GLASGOW;
AND
A. S. M. MACGREGOR, M.B., CH.B. GLASG.,
ASSISTANT PHYSICIAN.

INTRODUCTORY.

THE cases which form the material of this report came under notice during the recent prevalence of cerebro-spinal fever in Glasgow. They were admitted to the City of Glasgow Fever Hospital, Belvidere, during the two years May, 1906, to May, 1908. In May, 1906, the first admissions took place, and during the rest of that year cases continued to be admitted at the average rate of 7 per month. Early in 1907 the disease became epidemic, attaining its greatest prevalence in April when 42 cases entered Belvidere Hospital. Since that period there has been a gradual decline.

In the two years Belvidere Hospital received 330 cases of cerebro-spinal fever. Of these, 105 were treated with antimeningococcic serum, while 225 cases were not so treated. In a few examples the specific organism was not recovered, though the symptoms were typical of the disease. With these exceptions, the 330 cases were bacteriologically verified.

The four sera employed were Professor Wassermann's, Professor Ruppel's, Professor Kolle's, and Messrs. Burroughs, Wellcome and Co.'s. Wassermann's serum was given to 20 patients with 13 deaths; Ruppel's to six patients with five deaths; Kolle's to 20 patients with 14 deaths; and Burroughs, Wellcome and Co.'s to 56 patients with 34 deaths. Three patients, with two deaths, had more than one kind of serum. It is not proposed to base any opinion of the relative merits of the sera on the above figures, and the various sera will not be further distinguished.

Injection was at times subcutaneous and at times into the spinal canal. Not more than 25 cubic centimetres were injected at one time into the spinal canal. The intravenous method was also employed. Few cases had one injection only. Several had more than 10. The largest number of injections in a single case was 21. The serum reactions which followed repeated injection are discussed by one of us (Currie, 1908) elsewhere; abnormal phenomena were induced but none were of a dangerous character. Of the 105 cases one half had more than 50 cubic centimetres in all. Several had more than 500 cubic centimetres in all. The largest total for a single patient was 725 cubic centimetres.

Serum was in use continuously throughout the whole two years, but at no stage did all persons admitted undergo serum treatment. The type and severity of cases varied as the outbreak progressed, and the employment of serum for all cases entering hospital during any particular period would have left no cases of a like order to act as controls. The results of administration were thus checked throughout by control cases of a similar type and the fallacy was avoided of comparing the treated cases of one stage of the epidemic with the untreated cases of another.

In placing a value on antimeningococcic serum as used by us it has seemed fitting to approach the matter from two separate points of view. If the good results of serum administration be immediate and obvious it is plain that clinical observation of treated patients will afford evidence of the benefit received. We shall therefore consider in the first place the clinical aspect of the question. If, on the other hand, administration of serum be followed by no clinical signs of improvement, it may nevertheless be revealed by statistical inquiry into case mortality and the like that serum-treated cases profited in the end. We therefore propose in the second place to deal with the subject from the statistical side.

CLINICAL CONSIDERATIONS.

To convey a correct impression of the clinical appearances which followed our serum treatment it will be well first of all to indicate the forms in which the disease was manifest among our cases. This is desirable, not only on account of the rapid changes which may occur in the course of any single attack of cerebro-spinal fever but also because the general type of the disease may differ appreciably in different places and at different times. The case mortality, for example, is variously reported by observers; this will be referred to later. It will suffice in the meantime to note, from the clinical side, that Dunn (1908) in America had not seen or heard of a case of verified cerebro-spinal fever terminating by sudden crisis at an early stage, yet this form of recovery was familiar here.

The symptoms of the Belvidere patients have already been detailed by Dow (1908). For the purposes of this report the 330 cases under notice are classified in two groups: first, the group of acute cases; and, second, the chronic group.

Acute cases.—In the acute cases the symptoms were those of intense general infection. The onset, with severe headache and vomiting, was abrupt and often notably sudden. In a short time the patients became unconscious. Some remained deeply comatose; others had periods of extreme restlessness alternating with periods of coma. The faces of these patients were pale or cyanotic. Their eyes were bloodshot and often dotted with hæmorrhages. The symptoms of local infection in certain examples were limited to some nuchal stiffness with Kernig's sign, often not very definite, few cubic centimetres of sero-fibrinous fluid containing numerous polynuclears and some lymphocytes. In September another transient attack of polymorphous erythema occurred. A few days later hard nodules, at first tender, appeared over the patellæ to which they appeared to adhere. In October a fresh attack of bilateral pleurisy occurred. During all this time the temperature ranged from 100·4° to 103·1° and the patient rapidly wasted and became extremely pale, but the pulmonary lesions showed no signs of progress. In November the heart failed: the pulse was thready and there was acute dyspnœa; the liver was large and tender and a little ascites was present. Death occurred on Nov. 15th. Though tuberculosis was suspected it was not demonstrated during life. The oculo-reaction was positive, but the cytology of the pleural effusion was not characteristic and cultures of the blood on various media and inoculations of guinea-pigs were negative. At the necropsy only one organ showed lesions which were tuberculous to the naked eye; at the apex of the left lung was a grey translucent granulation of the size of a millet seed which microscopically showed the typical structure of a tubercle. Two tubercle bacilli were detected in it. At the base of the lung was a caseous tubercle of the size of a hemp seed. In none of the other organs were any lesions found which to the naked eye or to the microscope presented any nodular structure. The pleuræ showed some adhesions. The heart was much hypertrophied (580 grammes) and dilated. It was completely united to the pericardium by fibrous adhesions without any nodular formation even to the microscope. On the free borders of the mitral valve was a collar of very fine papillomatous vegetations. On the tricuspid valve were similar but less developed vegetations. The aortic valve was covered with irregular vegetations not so finely papillomatous as those on the mitral valve. Under the microscope all these vegetations showed a loose slightly fibrillar tissue rich in cells (lymphocytes and large connective tissue cells). The tubercle bacillus could not be found in them. There was a large nutmeg liver. In the pericranium no trace of the nodules present during life could be found. Similarly, the synovial membranes of the knees showed no traces of inflammation. On the contrary, the patellar nodules were present. They consisted of a wall of connective tissue containing abundant cells and a cavity filled with a substance like that found in hygromas. In the wall two tubercle bacilli were found. This case, like many recent observations, enlarges our conception of tuberculosis and shows that lesions may be produced which differ widely from those recognised and may spontaneously disappear.

THE COMPOSITION AND PHYSICAL PROPERTIES OF RENAL CALCULI.

IN the *Biochemical Journal* for August Dr. J. Sydney Rowlands reports the results of his investigations of a series of 22 calculi, which show that there is nothing in the appearance of a calculus that will give a trustworthy clue to its composition. The pigmentation, surface, and hardness which are usually relied upon for the classification of calculi are exceedingly untrustworthy, and it is by chemical analysis alone that their nature can be determined. The work has resulted in the discovery, at least so far as this series is concerned, that uric acid and its salts are very rare constituents of calculi. In 19 of the stones examined they were absent and in the remaining three only traces were found. Of equal importance is the unexpected fact that oxalic acid, combined usually with calcium, was found in each case, although it has hitherto been regarded as a much more rare constituent than uric acid. Phosphates were also commonly present, although they are usually considered as only occasional constituents. In regard to the physical property of hardness, on which stress has been laid by earlier observers, Dr. Rowlands considers that this property is determined by the rate and process of formation of the stone, as a compactly deposited glossy stone is the most difficult to crush, irrespectively of its composition. The degrees of smoothness and pigmentation appear to depend more on the rate of deposition and the amount of pigment present in the urine than on the chemical nature of the stone. The calculi were collected from widely distributed districts in South-west Lancashire and North Wales and were analysed by Haller's method.

THE RECENT SUDDEN HEAT.

THE vagaries of the British climate are never ending and they afford such just cause for astonishment that the national custom of making the weather the preliminary subject of conversation is quite natural and excusable. September, which, meteorologically speaking, is one of the autumn months, gave much better and more summer-like weather last year than the three real summer months, while this year, after behaving in a manner no way remarkable for three weeks and more, it suddenly became so hot that few days and still fewer nights during the preceding three months can be compared with it, and so humid that the effect of the unseasonable height of the thermometer was extremely trying even to the most healthy and robust. And the heat did not end with September, but showed no decided diminution until some days after the birth of October. The figures below show the shade readings of the maximum and minimum thermometer at various places in England, Wales, and Scotland for the five days Sept. 29th to Oct. 3rd and also the difference from the average and the number of hours of bright sunshine. In Ireland the weather was warmer than usual and very humid, but the heat was not generally excessive.

The general character of the weather was far more like the summer than the autumn type, for it was not until it had continued for two or three days that the temperature of the nights fell sufficiently low to permit the formation of the matutinal fog which is one of the characteristics of a fine September. As will be seen by the table, the mean of the daily maximum temperatures was from about 14° to 17° above the average and the mean of the minima about 7° to nearly 11° above. The mean temperature for the five days, which was nearly 67° in London and at Margate, and the extraordinary figure of 68½° at Aberystwyth, was everywhere much higher than the ordinary level for midsummer. The absolute maxima were 80° in some parts of London and also at Manchester, Bettws-y-Coed, and several places in the Midlands. The record for October, which goes back for our use of other sera besides that of Wassermann; rather we incline to the view that the acute phase of cerebro-spinal fever was specially virulent when the Glasgow epidemic was at its height and that for this reason many cases which came under treatment even in early days of their illness were already beyond the reach of remedies.

The treatment of 89 cases was begun during the first ten days of their illness—that is to say, between day 0 and day 9 inclusive; while the treatment of 16 was begun later than the first ten days of their illness—that is to say, on or after day 10. Among the 89 cases whose treatment was begun between day 0 and day 9, with 60 deaths, the case mortality was 67·4 per cent. Among the 16 cases in which treatment was begun on or after day 10, with eight deaths, the case mortality was 50 per cent. It emerges that the percentage of deaths among cases in which serum treatment was begun between day 0 and day 9 was higher than the percentage of deaths among cases in which treatment was begun on or after day 10. This result also differs considerably from the reports of others observers. Among Wassermann's 57 cases already referred to, 46 patients whose treatment was begun within the first 14 days—a period approximating to our 10-day period—had a mortality of 39·8 per cent.; while 11 patients whose treatment was begun outwith the first 14 days had a mortality of 81 per cent. Dunn (1908), as already noted, treated 15 cases with Flexner's serum. Of the 15 cases 12 patients at the time of his writing had recovered or were recovering, while three had died or ran the risk of dying. Of the 12 cured and hopeful cases all began serum during the first ten days of illness; of the three dead or doubtful cases all began serum treatment outwith the first ten days. The divergence of Wassermann's results from ours may again be explained as above by variation in the types of disease. The divergence of Dunn's results may be accounted for in a similar way. "It is possible," says this observer, "that my series included cases of an exceptional character." At least we think that the series in question included cases of a different order from many of ours.

Quantity of serum without reference to period of administration (Table III.).—With regard to the quantity of serum administered, the 105 serum-treated cases have been separated in Table III. into three divisions. Among 53 cases which had from 1 to 50 cubic centimetres of serum, with 37 deaths, the case mortality was 69·8 per cent.; among 18 cases which had from 51 to 100 cubic centimetres, with 12 deaths, the case mortality was 66·6 per cent.; and among 34 cases which had 101 cubic centimetres or more, with 19 deaths, the case mortality was 55·9 per cent. The percentages of the three divisions would thus appear to show a progressive diminution of the case mortality as the quantity of serum increases. Even if these differences were more significant than they happen to be it would be necessary to bear in mind that cases which received large totals of serum were cases which survived sufficiently long to be injected at repeated intervals and which had for this reason alone a certain prospect of recovery. Table III. does not make it plain that large doses of serum had a specially favourable influence.

Quantity of serum with reference to period of administration.—Table IV. shows details similar to those of Table III., considered with respect to cases whose treatment was begun within the first 10 days. The three divisions of Table IV. show a slightly higher case mortality than the three divisions of Table III., but preserve the same relation to one another. Table IV. affords no evidence that the administration of large quantities of serum, if begun between days 0 and 9, was of more value than the administration of similar quantities without reference to the period of beginning treatment.

Duration of Illnesses which ended in Death.

Average length of fatal illnesses without reference to period of administration of serum (Table V.).—Of serum-treated cases 68 proved fatal; the average duration of illness of the 68 cases was 26·44 days. Of untreated cases 179 proved fatal with an average duration of 19·75 days. The table as it stands suggests that in serum-treated cases which proved fatal death on an average occurred at a later period than in fatal untreated cases. It will, however, be necessary to analyse the group of fatal serum-treated cases with respect to the period at which administration of serum was begun before any conclusion can be drawn as to the relation between serum treatment and average duration of illness. This analysis is shown in Table VI.

Average length of fatal illnesses with reference to period of administration of serum (Table VI.).—Of 60 fatal cases in which serum treatment was begun in the first 10 days of illness the average duration of illness was 20·65 days. Of eight fatal cases in which serum treatment was begun after the completion of the first 10 days of illness the average duration of illness was 69·87 days. With reference to the latter class it is desirable to note that the eight cases which compose it must be looked on as in a sense selected cases, inasmuch as they had passed the acute phase of the disease during which in our experience the risk of speedy death was greatest. By detaching these eight cases from the total number of fatal serum-treated cases the result appears that the average length of illness of fatal cases whose treatment was begun in the period 0–9 was 20·65 days, a figure which differs by less than one day from the average duration of fatal untreated cases. The details of Table VI. therefore discount those of Table V. The evidence of the two tables together is insufficient to show that serum treatment had any definite influence in postponing the deaths of fatal cases.

Date of death without reference to the period of administration of serum (Table VII.).—The dates of death of cases are considered with reference to the two periods already defined, of which the first includes days 0 to 9 and covers the acute phase of the illness, while the second extends from day 10 onwards and covers the chronic phase. Among serum-treated patients the deaths were 68; of these, 35 took place in period 0–9, a percentage of 51·5; and 33 in period 10 upwards, a percentage of 48·5. Among untreated patients the number of deaths was 179, 92 in period 0–9, and 87 in period 10 upwards, percentages of 51·4 and 48·6 respectively. Alike for treated and untreated cases the percentage of deaths in both periods was close to 50. It does not therefore appear from Table VII. that the administration of serum affected the proportion of fatal cases in the two periods under notice.

Date of death with reference to period of administration of serum (Table VIII.).—In this table the fatal cases in which serum treatment began within the period 0–9 are detached from the total serum-treated cases of Table VII., and are compared in respect of the same considerations as before with the untreated cases. Of 60 fatal cases in which treatment began within the period 0–9, 35, or 58·3 per cent., of the patients died in period 0–9, and 25, or 41·7 per cent., in period 10 upwards. The difference between these percentages is in the sense that administration of serum within the period 0–9 was accompanied by a larger proportion of deaths within that period than occurred in untreated cases. It is, however, too slight to be significant and does not admit of any conclusion.

Duration of Illnesses which ended in Recovery.

Average duration of illness before permanent return of temperature to normal without reference to period of administration of serum (Table IX.).—Of serum-treated cases 37 of the patients recovered; the average duration of fever in the 37 cases before permanent return of temperature to normal, was 34·67 days. Of untreated cases there were 46 recoveries with an average duration of 30·23 days. The average duration of treated cases which recovered was greater by four days than the average duration of untreated cases which recovered. There is therefore no evidence from Table IX. that the administration of serum shortened the fever of cases which ended in recovery.

Average duration of illness before permanent return of temperature to normal with reference to period of administration of serum (Table X.).—Of 37 serum-treated patients who recovered 29 whose treatment was begun in the period 0–9 had illnesses with an average duration of 34·34 days. Eight patients whose treatment was begun in the period 10 upwards had on an average 35·87 days of fever. These data do not suggest that the administration of serum within the first 10 days of illness had any special value in shortening the course of the fever in cases which recovered.

Date of permanent return of temperature to normal without reference to period of administration of serum (Table XI.).—Among 37 serum-treated patients who recovered the fever lasted days 0–9 in four cases, or 10·8 per cent., and days 10 upwards in 33 cases, or 89·2 per cent. Among 46 untreated patients who recovered the fever lasted days 0–9 in marked decline in the necessary period of detention, but it probably also implies a decreased prevalence of the disease. It appears, however, that 737 children were admitted to this school during last year, raising the total number under treatment to 1075; of these, 673 were discharged cured and 46 were discharged at the request of the guardians before they were certified as cured, while two children died. The number of cases treated during the year by the x ray method was 508, of which 465 were discharged definitely cured and 43 were removed from the school at the request of the guardians. Of the 737 cases admitted to this school during the year 518 were classed by the visiting dermatologist (Dr. T. Colcott Fox) as cases of microsporon ringworm and 80 of endothrix trichophyton ringworm, while 139 were undetermined. The undetermined cases included some which were not ringworm, some cases treated before admission and practically cured, and some of ringworm of other regions than the scalp.

IS BERI-BERI IDENTICAL WITH EPIDEMIC DROPSY?

IN our recent annotation concerning the views of the identity of the above two diseases we adduced the evidence of Dr. T. F. Pearse, the health officer of Calcutta, in a paper of which he was the author, in its favour. It would appear, however, that other observers by no means agree with the views of Dr. Pearse: Captain D. Munro, I.M.S., and Captain T. H. Delany, I.M.S., reading papers at the Medical Section of the Asiatic Society of Bengal, gave no support to the above view. They demonstrated the constant appearance of anæmia of a marked degree with an increase in the proportion of leucocytes and also fever in all early and severe cases in epidemic dropsy, whilst these symptoms are said to be absent in beri-beri. Colonel Harris, I.M.S., also pointed out at the same meeting that in epidemic dropsy the knee-jerk was increased, whilst in all his cases of beri-beri there was absolute loss of the same from the first with one solitary exception where an increased knee-jerk was seen for one day only. He also drew attention to the before-mentioned absence of anæmia in beri-beri, and the very rare appearance of fever in the disease; and, lastly, whilst primary cardiac failure caused death in beri-beri, this was brought about by œdema of the lungs in epidemic dropsy. Captain M. McKelvie, I.M.S., furthermore drew attention to the presence of a rash in epidemic dropsy which was absent in beri-beri. On the other hand, Captain D. McCay, I.M.S., was inclined to think that beri-beri and epidemic dropsy were one disease. His experience of the state of the knee-jerks was such that he failed to differentiate the two diseases by any difference in this respect. Lastly, Dr. G. C. Chatterjee, who had had much experience of both beri-beri and epidemic dropsy at the Medical College Hospital, Calcutta, thinks that the two diseases are distinct. He also drew attention to the anæmia with low hæmoglobin value, which symptom was absent in beri-beri. In epidemic dropsy he had found the hæmoglobin as low as 20 per cent. and the red corpuscles only 1,200,000. He had never seen anæmia in beri-beri. The tenderness of the calves and loss of knee-jerk, so characteristic of beri-beri, were always absent in epidemic dropsy. Again, he points out that whereas in epidemic dropsy heart failure might occur, in beri-beri failure of the diaphragm was to be feared. There is thus seen to be considerable divergence of opinion from the views expressed by Dr. Pearse. The latter authority, however, in his reply to the discussion still maintained his opinion and repeated his argument that there was no one symptom by which these diseases could be absolutely distinguished. Although he made no attempt to controvert the statement of the above observers that anæmia and other blood changes were constant in epidemic dropsy but absent in beri-beri, yet there is a certain amount of truth in his observations; for instance, a case of beri-beri has been shown in which an increased knee-jerk has been present throughout the illness; and as regards the dread occurrence of heart failure in epidemic dropsy, this is the chief danger to be held in view in the case of beri-beri.

INFANT MORTALITY IN IRISH TOWNS.
